PORt PLANNING PARAMETERS

of the

Caribbean Basin

Prepared

by

Carl H. Plumlee

UN Regional Adviser in Ports & Harbours

PORt PLANNING PARAMETERS of the Caribbean Basin

Introduction

How much ocean cargo should be anticipated in a master development plan is a knotty question that often must be answered, at least temporarily, without the benefit of a detailed analysis such as should be made by transportation economists. In the final analysis the amount of cargo to be put through a seaport is the result of careful evaluations of the probable quantities of materials to be produced and consumed within identifiable zones and sub-zones of the island or the hinterland to be served by the port in question. The analysis is properly performed by economists who are especially skillful in relating the trends of population, and of production and consumption of industrial, forest, mineral and agricultural products to the quantities of materials that need to move from point to point. Mathematical modelists assist the economists in reaching conclusions as to how much of what kind of cargo will need to move through the port.

In the absence of a specific projection of future movements of cargo through the port or ports in question, what can be said of the requirement? It is presumed that all physical planning is based upon available estimates of certain basic criteria such as population, land area and national production, and even though such estimates may not be precise, it is reasonable to expect that estimates of total port traffic could be made of approximately similar validity. Thus, if it were believed that the gross national product would become a particular amount within a stated period, it might be possible to imply with equal confidence how the port traffic would change within the same period.

Scope of Investigation

In the quest for port planning parameters that may be useful for physical planning in the Caribbean Region, a search was made of available statistics concerning:

- (1) Population;
- (2) Land area;
- (3) Gross national product (GNP);
- (4) Gross domestic product (GDP);
- (5) Electric energy production; and
- (6) Ocean Cargo for each of thirty-five countries comprising the Caribbean Basin.

The amount of cargo moving through ports was considered in two scopes, including and excluding petroleum cargo. Thus seven factors were collected for each country and these are presented in the matrix of Table No. 1.

Source of Data

Statistics published by the United Nations and by the World Bank have been used to the extent available. These include mainly the World Bank Atlas 1971, the United Nations Statistics Yearbook 1971, and the United Nations Yearbook of National Accounts 1971. These and other sources are identified in the footnotes of Table No. 1.

Population figures and land areas were taken mainly from the World Bank Atlas 1971 for conditions existing in 1970. Gross domestic product data were taken mainly from Table No. 18 of the United Nations Statistical Yearbook 1971. Gross domestic product statistics were taken mainly from Table No. 14, Vol. III of the United Nations Yearbook of National Accounts 1971, for conditions existing in 1969 or 1970. Electrical energy production statistics were taken mainly from Table 139 of the United Nations Statistical Yearbook 1971 showing the latest data available, either in year 1969 or 1970. The amount of ocean cargo was taken from Tables 150 and 151 of the United Nations Statistical Yearbook 1971 for the latest year available, either in year 1969 or 1970. Where the aforementioned sources failed to provide the required data, statistics were obtained from documents and papers available in the UN ECLA Port of Spain files, as indicated in the footnotes of Table No. 1. There were some instances where none of the cited sources provided the desired information. There were 23 such instances within the matrix comprising 245 items of information, about nine per cent. In these instances judgement values were assigned by comparison with available

data. For example: if the gross national product figure was available and the gross domestic product figure was missing, the latter was assigned a value in approximately the ratio observed in other cases where both items are available.

Validity of the Data

The available ocean cargo statistics are for years 1969 or 1970, and the data for the other criteria are also mainly for years 1969 and 1970 but in any given comparison between ocean cargo and another planning criterion there are instances where the two components are not of the same year. It is considered that the out-of-phase displacement, to the extent of one year, in some instances, has little, if any, significant effect on the overall conclusions that may be drawn.

The Analysis

The current relationship between the annual volume of ocean cargo and each of the five aforementioned planning criteria was examined for each of the thirty-five countries of the Caribbean Basin, and this was done for two different scopes of ocean cargo, including or excluding petroleum cargoes. The tons of cargo per capita, per thousand square kilometers of gross area, per thousand US Dollars of GNP and of GDP, and per thousand kilowatt-hours of electrical energy was calculated for each country. The results are presented in Table No. 2 for the case of ocean cargo excluding petroleum, and in Table No. 3 for the condition when all cargo is included.

The extent that each of the five chosen planning criteria is correlated with the volume of ocean cargo is presented graphically in Figures I - V, inclusive, where the amount of ocean cargo excluding petroleum, is plotted against each of the five other criteria. Similar presentations could be made for the cases including petroleum.

Conclusions

The study indicates that for the region as a whole, none of the five planning criteria considered provides a specific parameter that would be valid for estimating the future amount of ocean traffic for

any unidentified island or hinterland of a port, for which the history of shipping is not previously known. However, the results may be useful because in most situations the history of shipping is available. The findings for each of the five criteria are discussed separately in the following paragraphs.

Population. The correlation between population and ocean cargo, less petroleum, is quite low, as may be seen on Figure II. The parameters range from 0.126 tons per person (Colombia) up to fourteen tons per person (Netherlands Antilles) and the correlation is much less when petroleum is included. The upper, lower and composite parameters are tabulated below for ocean cargo with or without petroleum.

TONS OF OCEAN CARGO PER PERSON

	<u>Excluding Petroleum</u>	<u>Including Petroleum</u>
three lowest cases	0.126 (Colombia) 0.169 (Guatemala) 0.185 (Haiti)	0.211 (Haiti) 0.334 (Guatemala) 0.400 (Colombia)
three highest cases	7.41 (Bermuda) 9.71 (US Vir. Is.) 14.0 (Neth. Ant.)	36.1 (Trinidad & Tobago) 130 (US Vir. Is.) 185 (Neth. Ant.)
Composite of All	1.28	5.57
High/Low Ratio	111	877

Area. The correlation between ocean cargo and gross area of the respective countries seems to be the least useful of the parameters considered, as may be seen on Figure I. Tons-per-square-kilometer vary over a very great range as shown below.

TONS OF OCEAN CARGO PER SQUARE KILOMETER

	<u>Excluding Petroleum</u>	<u>Including Petroleum</u>
three lowest cases	1.58 (French Guiana) 5.02 (Nicaragua) 8.04 (Guatemala)	1.89 (French Guiana) 7.55 (Colombia) 8.12 (Nicaragua)
three highest cases	2,150 (US Vir. Is.) 3,240 (Neth. Ant.) 7,580 (Bermuda)	8,260 (Bermuda) 28,700 (US Vir. Is.) 89,300 (Neth. Ant.)
Composite of All	29.0	131
High/Low Ratio	4797	47,249

Gross National Product. There is significant correlation between the amount of ocean cargo and the gross national product throughout the region, as may be seen on Figure III, although the parameter varies over a wide range as shown below:

TONS OF OCEAN CARGO PER 000\$US G.N.P.

	<u>Excluding Petroleum</u>	<u>Including Petroleum</u>
three lowest cases	0.371 (Colombia) 0.470 (Guatemala) 0.758 (Nicaragua)	0.929 (Guatemala) 1.17 (Colombia) 1.23 (Nicaragua)
three highest cases	10.3 (Jamaica) 14.9 (Guyana) 25.8 (Surinam)	42.0 (Trinidad & Tobago) 42.9 (US Vir. Is.) 278 (Neth. Ant.)
Composite of All	2.35	10.6
High/Low Ratio	69.5	299

Gross Domestic Product. The correlation between ocean cargo and gross domestic product is quite similar to the case of gross national product, as may be seen on Figure IV. The extreme cases are tabulated below:

TONS OF OCEAN CARGO PER 000\$US G.D.P.

	<u>Excluding Petroleum</u>	<u>Including Petroleum</u>
three lowest cases	0.315 (Colombia) 0.464 (Guatemala) 0.765 (Nicaragua)	0.917 (Guatemala) 0.994 (Colombia) 1.24 (Nicaragua)
three highest cases	9.43 (Guyana) 11.8 (Neth. Ant.) 25.3 (Surinam)	39.4 (US Vir. Is.) 41.7 (Trinidad & Tobago) 323 (Neth. Ant.)
Composite of All	2.22	10.0
High/Low Ratio	80	352

Electrical Energy Production. The correlation between ocean cargo and electrical energy production is the highest among the five parameters considered, as is shown on Figure V. The extreme cases are tabulated below:

TONS OF OCEAN CARGO PER THOUSAND KILOWATT-HOURS

	<u>Excluding Petroleum</u>	<u>Including Petroleum</u>
three lowest cases	0.218 (Br. Vir. Is.) 0.311 (Colombia) 1.18 (Nicaragua)	0.983 (Colombia) 1.81 (Costa Rica) 1.92 (Nicaragua)
three highest cases	13.1 (Grenada) 13.1 (French Guiana) 14.8 (Costa Rica)	30.8 (Trinidad & Tobago) 68.0 (Neth. Ant.) 172 (Antigua)
Composite of All	2.11	9.52
High/Low Ratio	68	175

General Conclusion. Although the port planning parameters that have been considered would probably be found to have limited value for estimating the amount of ocean cargo to be expected in an hypothetical situation (such as planning the development of "AIPOTU ISLAND"), the parameters applicable to each particular existing country may well be found useful for making the preliminary estimates prior to the realization of more detailed analyses.
