ACKNOWLEDGEMENTS

I am especially grateful to Angus Maddison for his help and encouragement during all phases of the investigation. Sergio Zamora was of great assistance during the initial phase and Nanno Mulder helped in the final stage of the study.

At ECLAC, I am grateful to Oscar Altimir and Fernando Fajnzylber, who helped to launch the investigation, and to Gloria Bensan, Mario Castillo, Mario La Fuente, Juan Mediano, Marcelo Ortúzar and Mónica Roeschmann, for their valuable support in the gathering and interpretation of the data.

I received useful comments from Derek Blades, Felipe Jiménez, Mark Keese, John Musgrave, Dirk Pilat, Víctor Urquidi and Michael Ward and from participants of seminars in ECLAC and the University of Groningen. Alan Heston kindly provided the purchasing power parities for Latin America.

I am also grateful to María Angélica van der Schraft who collaborated in the final editing of this paper.

I. INTRODUCTION

The lack of comparable estimates of fixed capital stocks between different Latin American countries has, since long, hindered the analysis of economic development within the region and comparison with other developing and developed countries. This article tries to fill part of this gap by providing estimates of gross and net fixed capital stock for six Latin American countries: Argentina, Brazil, Chile, Colombia, Mexico and Venezuela. These are part of an ECLAC project on long term economic development of Latin America using a growth accounting framework. The capital stock estimates will be related to other variables such as employment but, here we restrict ourselves to the presentation of the total capital stock series.

The estimates have been generated by employing the "Perpetual Inventory" technique currently used by most OECD countries to estimate their capital stocks and therefore the most appropriate in an international comparison. The analysis is concentrated on the methodology and results for Latin America but also include a comparison with Korea, Spain and the USA,¹ using the same methodology except for Spain. In this latter case I used a short-cut method which is useful in other (especially developing) countries where long term disaggregated series for investment are not available.

In spite of both the theoretical and practical difficulties with respect to the use, estimation and meaning of capital stock estimates, they continue to be extensively employed and are useful for many kinds of analysis, such as growth accounting, productivity analysis, economic forecasting, studies of cyclical fluctuations and of the relationship between capital, output and labour and the role of technical progress.

In the past several efforts have been made to estimate capital stocks in Latin America.² However no official time series of capital stock figures are prepared on a regular basis and the existing unofficial estimates have been made by autonomous researchers and institutes. This explains the great differences in methodology and coverage. These estimates can be useful for various types of analysis within each country, but are difficult to use for international comparisons because of differences regarding definitions and assumptions with respect to GDP, capital formation and its disaggregation, the use of initial stocks, the length of asset lives, retirement patterns (i.e. distribution of service lives around the mean life), and differences in the relative prices of assets.

As more and better data are now available, the United Nation's Economic Commission for Latin America and the Caribbean (ECLAC) considers it useful to make new capital stock estimates for Latin America, using a common methodology which makes comparisons possible within the region and with other developing and developed countries.

¹ The estimates for the USA come from the worksheets of Angus Maddison (1991) and have been slightly adjusted for changes in the benchmark year from 1985 to 1980 and for the use of somewhat different asset service life assumptions.

² For an overview of existing estimates of capital stocks in Latin America see the corresponding chapter in the (forthcoming) ECLAC publication "Long Run Growth in Latin America".

II. METHODOLOGY

There are basically two methods, each with its variations, to estimate capital stock:

- a) direct measurement of the capital stock for a benchmark year, through different types of surveys such as of physical assets, insured values or company book values or direct estimation on the basis of stock exchange values.
- b) by cumulating historical series on past capital formation and deducting assets which are scrapped, written off or destroyed by war.

The second method is widely known as the "Perpetual Inventory Method" pioneered by Raymond Goldsmith (1951). In this article annual fixed capital stock estimates are presented which were computed for the 1950-1989 period based on a perpetual inventory model.³ Our preference for the perpetual inventory model is based upon the fact that it uses a methodology which facilitates international comparisons and because it produces figures whose meaning is clearer because all the hypotheses and calculations are transparent and consistent and permits analysis of the structure and age distribution of the capital stock. It is now generally used in official estimates, sometimes combined with direct estimates of the initial stock, e.g. the Japanese statisticians use a postwar wealth survey benchmark.⁴

Capital assets considered consists of the various durable goods that are included in gross fixed capital formation in the national accounts. Generally the countries in this study follow the recommendations of the United Nations classification (United Nations, 1968) where gross fixed capital formation is defined as the outlays (purchases and own-account production) of industries, producers of government services and producers of private non-profit services to households, on additions of new durable goods (commodities) to their stocks of fixed assets less their net sales of similar second-hand and scrapped goods. Excluded are the outlays of government services on durable goods for military use. In general, the goods included are durable (lasting more than one year), tangible (intangible assets like patents and copy-rights are excluded), fixed (inventories and work in progress are excluded) and reproducible (natural forests, land and mineral deposits are excluded).⁵

We have separated capital formation by three asset types - residential and nonresidential structures and machinery and equipment. For each separate asset type we have estimated fixed capital stocks on the basis of past capital formation.

³ The description of this model is based upon Michael Ward (1976a).

⁴ See Angus Maddison (1991), Appendix D.

⁵ See Derek Blades (1989), p.3.

In this article we present estimates of both gross and net fixed capital stocks. This makes it possible to differentiate between "ex-post" and "ex-ante" notions of capital⁶ i.e. between actual and expected contributions of capital to production.

This study forms part of a research project in which these capital stock estimates are used basically for the explanation of the economic performance of six Latin American countries in comparisons with a sample of other developing and developed countries for the 1950-1989 period. Therefore, capital has been used in the "ex-post" notion, its observable role as a factor input in already realized production. For this reason the estimates of the gross capital stock, representing the total volume of the existing physical productive assets available and reflecting the original new cost of capital revalued to a common benchmark year's (1980) replacement prices, have been used in the study.

This "ex-post" notion should be distinguished from the "ex-ante" concept in which capital is used as an indicator of net worth which embodies potential economic services and has the capacity to generate income in the future. This net capital stock represents the cumulated "depreciated" value of the existing gross stock of capital. The present net worth of a capital asset, which is related to its future earning potential, progressively declines as it gets older even though the annual real value of its services may remain relatively unchanged over time.

The capital stocks have been valued at constant 1980 prices and in the Annex A to this working paper a source note is given for all, current and constant, series of GDP and capital formation used. GDP and capital stocks were then converted to international dollars by the International Comparison Project (ICP)⁷ PPP's rather than exchange rates. Separate PPP's for GDP, capital formation in residential structures, non-residential structures and machinery and equipment have been used.

The perpetual inventory method (PIM) estimates capital stock as a weighted sum of past gross investment flows. This involves the estimation of an initial capital stock consisting of the sum of past capital formation during the assumed lifetimes of the different asset categories. This initial stock can easily be updated on a yearly basis adding capital formation during the year and subtracting capital formation of assets that are withdrawn. The related net capital stock estimate can be obtained by applying an appropriate capital consumption coefficient to the gross capital formation values in the relevant period, or by deducting derived cumulated capital consumption estimates from the gross capital stock series.

To be able to use the perpetual inventory method historical time series of gross fixed capital formation were needed over a long period of time, basically since 1900. These time series,

⁶ See Ward (1976a), p.19-20.

⁷ The ICP was a joint responsibility of the United Nations Statistical Office, the World Bank, and the International Comparison Unit of the University of Pennsylvania. Alan Heston kindly provided the 1980 PPP's for GDP and capital formation for the Latin American countries (including Mexico) which were somewhat revised as compared to the ones published in United Nations and Eurostat (1987).

which are especially long for Latin America where in many cases official series do not go back further than 1950, were needed for GDP, GDP without residential construction and gross fixed capital formation broken down in machinery and equipment, residential and non-residential structures.

The precision of the model depends primarily on the accuracy of these basic data. In the Annex A of this article we present therefore a detailed description of the sources and series used for each country. This Annex includes a set of three Tables for each Latin American country which present long term series (1900-1989) for GDP at constant 1980 national prices, GDP at constant 1980 international dollars, population and GDP per capita (Table 1). In the Tables 2 and 3 long term (1900-1989) gross total and disaggregated investment in national currencies and as a percentage of GDP. At the same time this Annex contains the explanation of procedures applied in case no series were available and we had to construct them. For most of our countries it was relatively easy to get information back till 1925 (except for Venezuela were time series were only available back to 1937) although for example capital formation in residential construction gave problems for the whole period in some countries. However, for the period 1900-1925 we were obliged to construct most of the basic series.

We have assumed a working life of 50 years for residential structures, 40 years for other structures and 15 years for machinery and equipment, for all countries, over the whole period. These assumptions seem rather realistic for non-residential structures and machinery and equipment. Several countries use asset life estimates which come close to ours (e.g. the asset lives which the BEA uses are on the average practically the same as ours, although the official US estimates are more finely disaggregated). In the case of residential structures the asset life of 50 years is probably rather low but it is practically impossible to obtain data regarding capital formation in residential structures before 1900 in Latin America and therefore we have adopted the 50 years asset life assumption.⁸ The objective of this study was to generate capital stocks for the 1950-1989 period. In order to be able to generate the initial total capital stock for 1950 capital formation in machinery and equipment was needed since 1935, in non-residential construction since 1910 and in residential construction since 1900.

One characteristic of the perpetual inventory method is that errors in the estimates of early capital formation become progressively less important as such investment represents a diminishing proportion of the current total stock in existence.

The model described above produces a "capacity stock" of capital.⁹ This includes all capital assets but some of these may be temporarily idle and others may have been withdrawn from production and held in reserve in case they may be needed to meet an unexpected rise in

⁸ The official estimate of the U.S. Department of Commerce (1987), uses a service life of 80 years for new, 1-4 unit structures and 65 years for new, 5 or more unit structures. However, for additions, alterations, major replacements and some other items service lives are much lower so the average service life might be well below 80 or even 65 years.

⁹ See Colin Campbell (1977), quoted in Blades (1989), p.6.

demand. So the PIM will not produce estimates of the "utilized stock". The service lives used in this method refer to the total length of time from the initial installation of assets to the moment when they are finally scrapped. Clearly these lives may include periods when the assets are not being used to produce anything.

Together with the above mentioned working lives for the assets we have assumed a rectangular retirement pattern, that is, assets are completely scrapped after serving their respective lives (15, 40 and 50 years). These assumptions about the mortality function and the fixity of service life have been adopted for reasons of data availability, transparency and simplicity.

Blades analyses in detail these different assumptions. In our model we use a simultaneous exit mortality function which is also still in use in Canada, Japan and Norway. Simultaneous exit may be regarded as a limiting case of a bell shaped function which Blades considers the only plausible candidate for a mortality function and although its assumptions are clearly unrealistic, i.e. all assets of a given vintage disappear simultaneously, its results are not very different from the bell shaped.¹⁰

A big problem in this kind of research is the estimation of the length of life of the capital assets. Not much empirical information about service life is available, especially not in the Latin American countries.¹¹ Changing service life assumptions affects the estimated size of the capital stock but also affects its rate of growth. We have applied a uniform constant 50, 40 and 15 years of asset life (in residential structures, non-residential structures and machinery and equipment respectively), which facilitates international comparisons although there exist of course differences in asset lives in and between countries.

Another aspect is whether or not the average service lives remain constant in time as we have assumed. The service life of a given type of asset almost certainly varies both between different users and from one period to another. When business conditions are favorable assets will be used more intensively and discarded sooner. Blades concludes that: "There is, however, no evidence of any secular tendency for given types of assets to be retained in production for longer or shorter periods".¹² This of course does not mean that the average service life of the aggregated capital stock also remains constant because this depends also from the distribution of the different assets in the stock.

For developing, especially Latin American countries these length of life assumptions may be critical as they are often not only related to technological and economic considerations but also to shortages of foreign exchange and the absence of regular repairs and maintenance because of budgetary constraints. Furthermore the obsolescence of capital seems to be less significant

¹⁰ See Blades (1989), Figure 2, p.25.

¹¹ Well-known studies regarding the USA are the studies by Terborgh (1954) and Winfrey (1935).

¹² See Blades (1989), p.39.

than the collapse of the product market in determining both use and utilization rates. Future research should clarify the relative importance of these issues in Latin American capital stock estimates.

For the calculation of net capital stock one has to define a depreciation function for allocating the cost of the asset over its service life. Actually there exists no agreement over this depreciation function but in the literature two approaches step out. The first is the straight-line pattern of depreciation in which the efficiency declines linearly over the lifetime of the capital good. A second method, also used with some frequency is the so-called declining balance depreciation in which efficiency of the capital good declines geometrically.

In order to obtain the net capital stock in this study we have chosen the first method, assuming that the capital services are used up in equal installments over time, i.e. applying straight-line depreciation over the working life of the different types of assets. We also assumed that the obsolescence value at the end of the economic life of the capital good is zero, which is of course often not the case, but this treatment of obsolescence simplifies in great deal the calculating procedure. This procedure is used in several of the OECD countries for the estimation of net capital stock, but also other definitions of depreciation for allocating the cost of the asset over its service life can be used.

A model layout for capital stock estimation was developed to make all procedures transparent and to facilitate the replication of these results by other researchers (see Tables 1-3 of Annex B) but we also give here the algebra of our procedures. In Table 1 of Annex B an example is presented of the procedure for estimating alternative benchmark capital stocks in non-residential structures at 31 December 1949, procedure which is the same for each country. Also the procedure is the same for each category of capital formation and the only difference is that in the case of residential capital stock the series start in 1900 and in the case of machinery and equipment in 1935.

In order to go step-by-step through this example we use capital stock estimation in non-residential structures in Argentina. The gross gross increment to capital stock of column 3 results from the multiplication of GDP at 1980 constant prices in column 1 and the ratio of total gross fixed capital formation in construction to GDP at constant prices in column 2. End 1949 gross fixed capital stock in construction equals the sum of 1910-1949 gross fixed capital formation or gross increments to capital stock as given in column 3.

The initial end year gross capital stock was calculated as follows:

$$GGI_t^i = a_t^i * GDP_t \quad (1)$$

$$GK_b^i = \sum_{m=b-\theta+1+j}^b GGI_m^i \quad j = 0, \dots, (\theta-1). \quad (2)$$

where:

- GK^i_b : Gross Initial Capital Stock of asset i at b
- GGI_t^i : Gross Increment to Capital Stock of asset i during period t
- GDP_t : Gross Domestic Product in t
- a_t^i : Ratio of Total Gross Fixed Capital Formation of asset i to GDP at constant prices in t
- b : Initial year
- θ : Length of life of asset i
- i : Type of asset
- t : Time

Column 4 presents the annual depreciation provision based upon straight-line depreciation which means that, in each year in which depreciation takes place, 1/40th of the capital formation is depreciated. Column 5 gives the yearly components of depreciated capital formation remaining by end 1949, corresponding to 1/40th for 1910, 2/40th for 1911 etc. End 1949 net stock consists of the sum of 1910-1949 components of depreciated capital formation which equals 1910-1949 sum of column 5. Net mid year capital stock was calculated as follows:

$$D_t^i = \frac{1}{\theta} \sum_{m=t+1-\theta}^t GGI_m^i \quad (3)$$

$$NK_b^i = \sum_{m=b-\theta+1+j}^b \frac{(1+j)}{\theta} * GGI_m^i \quad (4)$$

where:

- D_t^i : Depreciation of asset i during t
- NK_b^i : Net Initial Capital Stock of asset i at b

The index of vintage effect in column 6, which represents embodied technical progress, assumes a steady yearly rate of technical progress in the case of non-residential structures of 1 per cent (as compared to 0.5 per cent in the case of residential structures and 2 per cent in machinery and equipment). These estimates have been made to be able to give the capital stock a quality improvement in our growth accounting exercise Columns 7, 8 and 9 equal columns 3, 4, and 5 adjusted for the vintage effect, i.e. multiplied by column 6. So end year 1949 vintaged gross stock equals 1910-49 gross gross vintaged increment to capital stock. End year 1949 vintaged net stock equals the sum of 1910-1949 vintaged components of depreciated capital formation which equals 1910-1949 sum of column 9, and all the above formulas should be adjusted in case of gross and net vintaged capital stock estimation.

This procedure of benchmark year capital stock estimation can of course also be used to estimate the 1950-89 end year net and gross (vintaged) capital stocks. Alternatively the procedures which are detailed in Tables 2 and 3 of Annex B can be applied. In these tables capital stock estimates for the 1950-89 period are elaborated. In Table 2, 1950 end year gross capital stock (column 6) equals the benchmark end year 1949 capital stock plus the gross gross increment in capital stock in 1950 as given in column 3 minus retirement of gross gross increment to capital stock of 40 years ago (column 4). The 1950 end year net stock equals the 1949 stock plus the gross gross increment to capital stock (column 3) minus annual depreciation (column 7). The respective net and gross end year capital stock series were calculated as follows:

$$GK_t^i = GK_{t-1}^i + GGI_t^i - GGI_{t-0}^i \quad (t>b) \quad (5)$$

$$NK_t^i = NK_{t-1}^i + GGI_t^i - D^i t \quad (6)$$

where:

GK_t^i : Gross Capital Stock of asset i and t

NK_t^i : Net Capital Stock of asset at t

Columns 10 and 11 of Table B2 present average ages of gross and net capital stocks respectively and in column 12 and 13 the end-year gross and net capital stock estimates are brought to a mid-year basis. Finally, column 14 gives the average of mid-year net and gross capital stocks. The formulas for the calculation of average age and re-adjustment to mid-year¹³ are given below. Finally the formulas for total gross and net capital stock aggregation and total gross and net capital stock average age calculation are presented.

13 The calculation procedure comes from Ward (1976a), p.58 who calls this the approximate method.

$$AAGK_t^i = \frac{\sum_{m=t-\theta+1+j}^t (\theta-j) * GGI_m}{GK_t^i} \quad j=0, \dots, (\theta-1) \quad (7)$$

$$AANK_t^i = \frac{\sum_{m=t-\theta+1+j}^t \frac{j+1}{\theta} * (\theta-j) * GGI_m}{NK_t^i} \quad (8)$$

$$GMK_t^i = \frac{GK_{t-1}^i + GK_t^i}{2} \quad (9)$$

$$NMK_t^i = \frac{NK_{t-1}^i + NK_t^i}{2} \quad (10)$$

$$TGK_t = \sum_{i=1}^n GK_t^i \quad (11)$$

$$TNK_t = \sum_{i=1}^n NK_t^i \quad (12)$$

$$AAGK_t = \frac{\sum_{i=1}^n AAGK_t^i * GK_t^i}{TGK_t} \quad (13)$$

$$AANK_t = \frac{\sum_{i=1}^n AANK_t^i * NK_t^i}{TNK_t} \quad (14)$$

where:

$AAGK_t$: Average Age of Gross Capital Stock of asset i in t

$AANK_t^i$: Average Age of Net Capital Stock of asset i in t

GMK_t : Gross capital stock, mid-year t

| | |
|----------|---|
| NMK_t | : Net capital stock, mid-year t |
| TGK_t | : Total Gross Capital Stock in t |
| TNK_t | : Total Net Capital Stock in t |
| $AAGK_t$ | : Average Age of Total Gross Capital Stock in t |
| $AANK_t$ | : Average Age of Net Capital Stock in t |
| n | : Number of assets i |

In Table 3 of Annex B the procedure for estimating alternative variants of 1950-1989 capital stock with vintage adjustments is shown with in column 14 and 15 the resulting mid-yeared net and gross capital stock and in column 16 the average of mid-year net and gross stocks.

III. RESULTS

In Tables of Annex C of this article a complete set of net and gross capital stock estimates are presented for each country: i.e.; Table "Country" 1: Gross and Net Fixed Tangible Capital Stocks by Type of Asset, 1950-1989 at constant 1980 national prices; Table "Country" 2: the same as Table "Country" 1 but at constant million 1980 international dollars; Table "Country" 3: Capital Stock: Average Ages, Average Service Lives and Capital-Output Ratios, 1950-89 on the basis of national currencies and Table "Country" 4 which is the same as Table "Country" 3 but now calculated on the basis of international dollars.

1. Comparison of National and Standardised Estimates

In a previous paper a detailed comparison of the existing capital stock estimates in Latin America and the new ones which have been elaborated in this article was made, see Hofman (1990). Table 1 presents a confrontation these national estimates with our standardised capital stock. In this Table we only present the most recent estimates. The existing estimates very often have been made for different time periods and we present those closest to our benchmark years. For Argentina the Goldberg/Ianchivolici (1988) is an excellent study which is also the only existing estimate completely based upon the perpetual inventory method. The differences with the standardised estimates come mainly from the different assumptions regarding service lives of the assets which is much higher than in the case of the standardised estimate. As a result the Goldberg/Ianchivolici (1991) study has higher fixed capital stock levels and lower growth rates than our estimate.

In the case of Brazil estimates of Goldsmith (1986) and Langoni (1974) were included. The Goldsmith estimate is largely based upon the study by Langoni which is one of the few dealing with the problem of fixed capital stock estimation in Brazil. However his initial fixed stock estimate seems rather high and the falling capital-output show a tendency contrary to ours. The tendencies of the capital-output ratio in the Chilean case coincide with ours but again the initial stock estimate based, in both cases, I.E. Urrutia (1983) and Haindl/Fuentes (1986), upon a methodology developed by Harberger (1976), is rather high.

In Colombia the estimates of Harberger (1976) coincide largely with ours as well as in levels as in tendency of capital-output ratio, the more recent estimates of Henao (1983) show much higher levels and a clear downward tendency of the capital-output ratio. Finally the Mexican estimates by the Banco de Mexico (1969 and 1985) show very distinct levels and tendencies and are by the lack of methodological information very difficult to interpretate.

Table 1

A CONFRONTATION OF OUR ESTIMATES OF FIXED CAPITAL STOCKS WITH EXISTING
ON THE BASIS OF GROSS AND NET CAPITAL/OUTPUT RATIOS, 1950-89

| | Argentina | | Goldberg/Ianchilovici (1988) | |

2. Standardised Estimates

In Table 2 we present the exchange rate and purchasing power parities (PPP) used in this study to calculate GDP and the different components of capital formation in 1980 international dollars. These are the revised results of Phase IV of the International Comparison Project and differ in some cases from the PPP's published in United Nations and Eurostat (1987). Also enclosed are the PPP's for Mexico which were originally not published. By also presenting the capital stocks at national currencies we give the potential user the possibility to use other PPP's or exchange rates than the ones used by us. Applying these disaggregated PPP's has a great impact on the capital stock levels as will be shown below.

Table 2

**EXCHANGE RATE AND PURCHASING POWER PARITIES WITH RESPECT TO THE INTERNATIONAL
DOLLAR FOR GDP AND COMPONENTS OF CAPITAL FORMATION, 1980
(National currency units per international dollar)**

| | Exchange Rate | GDP | Non-Residential Structures | Residential Structures | Machinery and Equipment |
|-----------|---------------|-------|----------------------------|------------------------|-------------------------|
| Argentina | 1837 | 2709 | 4670 | 4057 | 3899 |
| Brazil | 52.7 | 30.6 | 25.0 | 32.0 | 47.0 |
| Chile | 39.0 | 28.8 | 27.0 | 52.1 | 50.7 |
| Colombia | 47.3 | 23.1 | 22.3 | 19.6 | 54.8 |

Source: The PPP's for Latin America were kindly supplied by Alan Heston of the University of Pennsylvania and former Director of the International Comparison Project (ICP). Exchange rate and PPP's for other countries from United Nations and Eurostat (1987).¹⁴

Table 3 presents the deviation index of the different PPP's with respect to the exchange rate in 1980 and it becomes clear that there are rather big differences. All countries, with the exception of Argentina which has a 32 per cent lower exchange rate, have much higher exchange rates than PPP's as can be seen in column 1 which gives the total GDP PPP/exchange rate deviation index. The range goes from .49 in Colombia to 1.47 in Argentina. This implies that for all countries, except Argentina, a conversion from national currencies to international dollars gives higher GDP's than in the case of conversion with the exchange rate. In case of the PPP's of the components of capital formation the pattern is not as uniform although the deviation index of machinery and equipment is higher in all cases except Spain and the USA (see column 4 and 1). Non-residential structures PPP's are generally lower (column 1 and 2).

¹⁴ The estimates for the Latin American countries are somewhat different from the ones published in United Nations and Eurostat (1987). Big differences occurred in the cases of Argentina and Chile where a computational error was made.

Table 3

PPP / EXCHANGE RATE DEVIATION INDEXES, 1980

| | GDP (1) | Non-Residential Structures (2) | Residential Structures (3) | Machinery and Equipment (4) |

Source: Table 2.

By developing the above described model layout for capital stock estimation all procedures have been made transparent.¹⁵ For each country also a detailed description and explanation is given of all sources and series used in the elaboration of our final 1980 constant prices series.¹⁶

Tables "Country" 3 and "Country" 4 of Annex C present for each country average ages of total and non-residential gross and net capital stock, the total and non-residential average service life and the capital-output ratios for the 1950-89 period, both on a national currencies basis as well as in international dollars.

The average age of the capital stock has been estimated giving each vintage of capital formation as a weight the number of years it formed part of the capital stock (which in the case of machinery and equipment is a minimum of 1 year and a maximum of 15 years). The average life expectation of the capital stock has been estimated by dividing the gross stock of a given year by the depreciation allowance in the same year. As we use straight-line depreciation this gives a reasonable estimate of average service life.¹⁷

Table 4 presents a summary of the results with respect to average service lives. It becomes clear that average service lives go down in all countries (except for Brazil) from 1950-80 and remain almost constant afterwards. As we have assumed fixed asset lives for the separate assets this shortening of lives is caused by changes in the composition of the capital stock, basically an increase of machinery and equipment and a decrease of residential structures (see also Tables 9 and 10).

¹⁵ See for an example of this lay-out Annex B and for its complete description the pages above.

¹⁶ See Annex A

¹⁷ See Maddison (1982), p.216.

In Table 5 levels of total and non-residential gross fixed capital stock are presented on a per capita basis and we also give the levels compared to the USA. The comparative level fell in Argentina, Chile (which both had rather high initial levels) and Colombia and rose in the other countries. The extremely fast growth of Korea's stock is reflected in the fact that it's per capita level was the lowest of all in 1950 and has risen above all Latin American countries in 1989.

Source: Annex C and D.

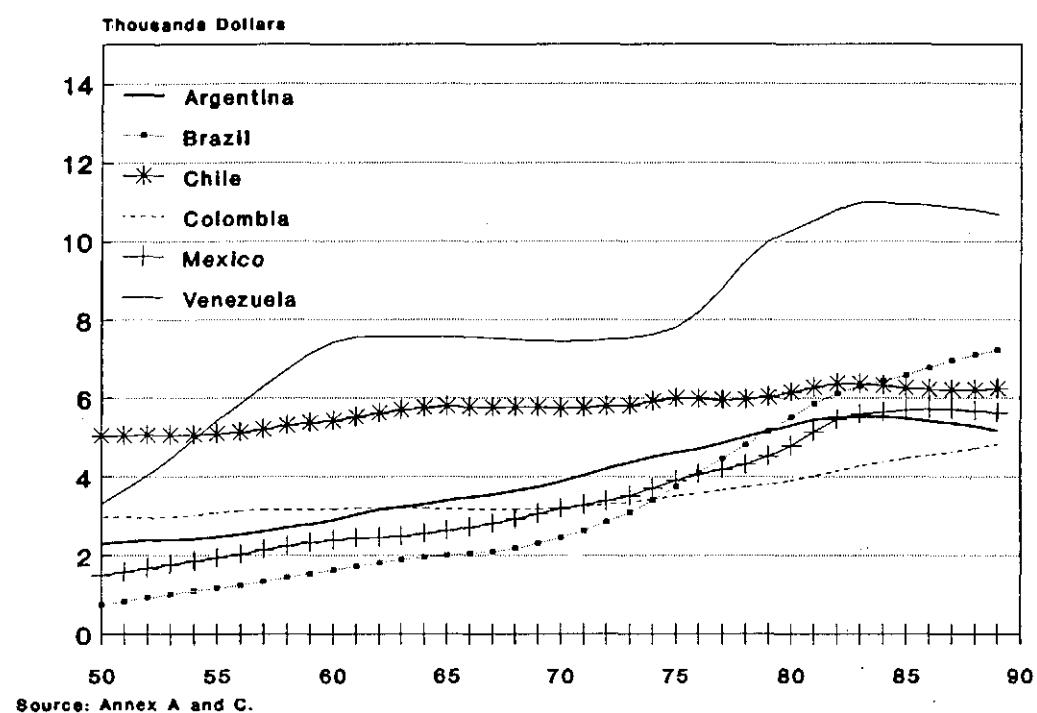

Graph 1 presents the growth of gross total fixed capital stock per capita in the six Latin American countries. Here the impressive growth in Brazil and Mexico in 1950-89 becomes quite clear. Another aspect that draws attention in this graph is the fact that Argentina and Chile had high total fixed capital stock per capita levels in 1950 but had fallen far behind Brazil and Mexico in 1989.

The growth performance of Venezuela is also quite impressive, starting from a rather low level in 1950 its per capita stock grew initially very rapidly, reaching the highest level in Latin America in the late fifties. After a new growth sprint in the seventies, result of the oil crisis, and stabilizing in the 80s Venezuela still maintains the highest level per capita in Latin America. Chile, Argentina and Colombia all have experienced rather steadier growth.

Graph 2 shows the growth of total fixed non-residential capital stock per capita in our sample of Latin American countries for the 1950-89 period. This graph is of course very similar to Graph 1 but there are also some interesting differences. The total non-residential capital stock represents better than the total capital stock the productive capacity of a country, and is therefore a more appropriate measure in, for example, a growth accounting exercise. With respect to the results it is clear that Brazil has been the fastest growing country. Very similar with graph 1 is the impressive growth of per capita total non-residential capital stock in Venezuela. Colombia, which non-residential capital stock per capita grew steadily but not very fast. Other low performers are Chile and Argentina.

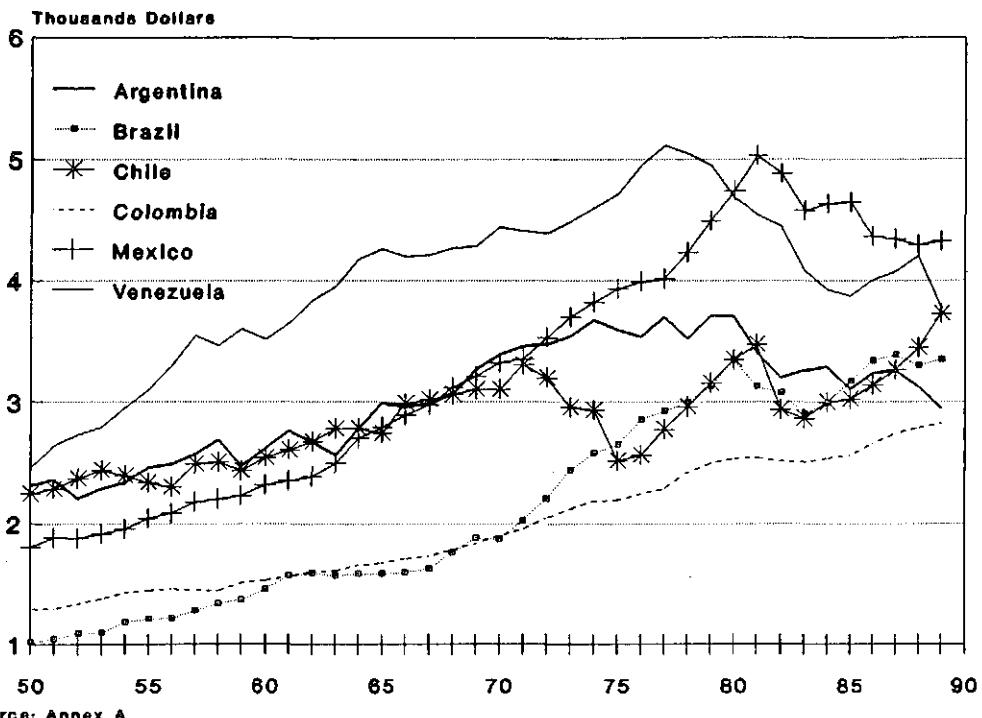

Graph 2
Latin America: Total Non Residential
Capital Stock Per Capita, 1950-89

Source: Annex A and C.

Graph 3 shows the development of GDP per capita in the sample of Latin American countries measured in international dollars during the 1950-89 period. This picture is of course well-known and confirms once again that Colombia is the country which experienced a process of steady growth (the same as in the case of the total fixed per capita capital stock) almost during the whole period. This has not been the case in the other countries where the crisis has hit hard. Brazil and Mexico grew steadily at high rates (well over 6 per cent) during the 1950-80 period but the 1980-89 period has been disastrous with almost no growth in GDP which means a decline on a per capita basis. The situation has been worse in Argentina and Venezuela where GDP only grew until about the mid seventies and afterwards stagnated or even declined. An exception is the case of Chile where the growth process several times has been interrupted by severe crises, as was the case in the beginning of the seventies and the eighties, and causes a rather weak growth performance over the 1950-89 period.

Graph 3
Latin America: GDP per Capita, 1950-89

Source: Annex A.

In Tables 6-9 the graphical presentation of Graphs 1 and 2 (which only show gross fixed capital stock per capita) is illustrated in more detail. Table 6 and 7 give annual average compound growth rates for total capital stock and non-residential capital stock for the 1950-89 period. With respect to their growth rates these countries can distinctly be divided in two groups: The fast growers Brazil, Mexico and Venezuela and the slower growing group of Argentina, Chile and Colombia.

Table 6

LATIN AMERICA: TOTAL GROSS CAPITAL STOCK, 1950-1989
 (annual average compound growth rates)

| | 1950-73 | 1973-80 | 1980-89 |

Table 7 presents the growth rates for gross non-residential capital stock which are, in comparison with the growth rates of gross total stock, somewhat higher in four countries (Argentina, Brazil, Chile, and Venezuela) and lower in Colombia and Mexico in the 1950-80 period. For the 1980-89 period the growth rate of non-residential capital stock, compared to total stock, is lower in almost all countries.

Table 7

LATIN AMERICA: GROSS NON-RESIDENTIAL CAPITAL STOCK, 1950-1989

The relationship between the growth of the net and gross stocks depends on the history of capital formation. When growth decelerates as in the 1980-89 period gross stock will grow more rapidly than net stock, as happened in all countries, and the inverse is true in periods of growth acceleration. During 1950-1980 net stock grew faster in Argentina and Brazil. The growth rates of both stocks were about the same in Colombia and Mexico indicating a process of steady growth. For Chile and Venezuela the period 1950-89 was not homogeneous as both had a sub-period of faster and one of slower growth of net stock compared to gross.

Table 8

Applying the PPP's of Table 1 to the different components of capital has a considerable effect on the level of the capital stock as becomes clear from the capital output ratios presented below. Here we are interested in the effect on the growth rates of the different stocks. Growth rates in international dollars may be different from those in national currencies because the PPP's change the composition of the capital stock. The sign of the change in the growth rate will depend on these compositional changes.

Table 9 gives an indication of changes in the composition of gross total capital stock, measured in international dollars, during the 1950-89 period. In all countries (except Brazil which had the highest share of all countries in 1950) the share of machinery and equipment in the total capital stock increased from 1950 to 1980 and stabilized or fell somewhat during 1980-89. The share of residential structures fell in Argentina, Brazil and Venezuela and it rose in Mexico, Colombia and Chile. Non-residential's share increased in Brazil and Argentina and fell in the other countries. A comparison of Tables 9 and 10 shows that measurement in international dollars or national currency makes a big difference in the composition of the capital stock. This effect, very notable in the cases of machinery and equipment in Chile and Colombia, causes some assets to fall to extremely low levels.

Table 9

Table 11 compares the growth of capital stock measured in national currencies with our preferred measure in international dollars. Argentina, Mexico and Venezuela show very small differences between the two growth rates. In the other countries the differences are bigger. There are sometimes differences over 10 per cent in the growth rates especially in the 1980-89 period when growth was slow. For the 1950-80 period only Colombia showed differences of over 10 per cent in non-residential capital stock.

*: Difference calculated as: growth rate in international dollars - growth rate in national currency.

Table 12 presents the ratio of non-residential capital stock to the total capital stock. This ratio can be seen as an indicator of the participation of the productive capital stock (measured as the non-residential stock) in the total stock.

The initial 1950 ratio of productive to total fixed capital was very low in Argentina where residential capital stock is bigger than non-residential. The other countries had much higher productive capital stock participation levels - Brazil having the lowest and Colombia the highest. In 1989 at the end of the period under consideration Argentina remains the country with the highest level of residential capital stock but now Mexico has definitely the highest levels of residential capital stock. The role of productive capital is more dominant in the other countries of which Venezuela has the lowest residential capital stock levels.

Source: Annex C.

In the following tables estimates for capital-output ratios are presented. There are many forces, such as technical progress, capital widening or capital deepening, demand and supply factors and other classical factors such as the rate of interest and problems of allocation and distribution, that affect the development of the capital-output ratios. An attempt to explain its development for 9 countries during a 39 years period does not fall within the objective of this article. We do however include these estimates because they are used rather intensively in economic analysis such as economic forecasting, planning and econometric models.

In Tables 13-16 a comparison of capital-output ratios of total and non-residential capital stock for the 1950-89 period is made. In Tables 10-12 these comparisons are based on estimations in international dollars and in Table 13 a comparison is made of differences in outcomes between estimates in international dollars and national currencies.

Table 13 shows clearly that in 1950 the countries had rather different gross capital-output ratios, Chile having the highest and Brazil and Mexico the lowest. This situation has changed at the end of the period under consideration, when Venezuela reached the highest levels and Colombia and Chile are amongst the lowest. During the 1950-89 period, the capital-output ratios of Chile and Colombia have remained more or less stable while the ratios of the other countries have risen substantially.

Table 13

TOTAL FIXED GROSS CAPITAL-OUTPUT RATIOS, 1950-89
 (In 1980 international dollars)

| | 1950 | 1973 | 1980 | 1989 |
|--------------------|------|------|------|------|
| Argentina | 2.1 | 2.2 | 2.4 | 3.1 |
| Brazil | 1.2 | 1.8 | 2.2 | 3.0 |
| Chile | 3.2 | 2.8 | 2.6 | 2.4 |
| Colombia | 2.7 | 2.1 | 2.1 | 2.3 |
| Mexico | 1.2 | 1.8 | 1.9 | 2.6 |
| Venezuela | 1.8 | 2.1 | 2.7 | 3.5 |
| Arithmetic Average | 2.0 | 2.1 | 2.3 | 2.8 |

Source: Annex C.

The gross non-residential capital-output ratios (Table 14 shows quite different and obviously much lower ratios than the ones in Table 13. In 1989 the gross capital-output ratio of Venezuela (the highest) was about 50 per cent higher than the ratio in Colombia (the lowest). With respect to gross non-residential capital-output ratios in 1989 this spread was much higher (115 per cent) with Venezuela again the highest and Mexico being the lowest. This difference in spread between total capital and non-residential capital-output ratios can be observed for the whole 1950-89 period.

Table 14

GROSS NON-RESIDENTIAL FIXED CAPITAL-OUTPUT RATIOS, 1950-89
 (In 1980 international dollars)

We have seen in Table 11 that the comparison of the growth rates of capital stock in national currencies and international dollars does not yield very big differences. However the results of Table 16 show that a comparison of capital-output in national currencies or international dollars makes a significant difference.

The conversion of GDP and capital stock from national currencies to international dollars has a great impact on their respective levels. From Tables 1 and 2 it becomes clear that the PPP's for GDP in the Latin American countries are generally lower than the exchange rate (with the exception of Argentina, see Table 2, column 3) and this causes an increase of the GDP level compared to the level measured with the exchange rate. The PPP's of the different components of the capital stock are generally higher than the PPP for GDP (see Table 1) and this causes a big decline in capital stock levels as compared to GDP.

IV. LATIN AMERICAN EXPERIENCE COMPARED WITH KOREA, SPAIN AND THE USA

In this section we will shortly compare our outcomes with respect to capital stock with some other countries, especially Korea, Spain and the USA. For Korea and the USA we have used exactly the same methodology as in the case of the Latin American countries. However in the case of Spain we introduce a short-cut method because the data available for that country does not permit an application of our standard method. In Annex D a detailed description of this short-cut method and its results is given.

We can now proceed with the presentation of the results for Latin America in comparison with Korea, Spain and the USA. In order to have a clear overview of these results we present the three above mentioned countries together with Brazil, Chile and Venezuela. Table 17 shows the annual average compound growth rates of the total gross capital stock during the 1950-89 period. In the first sub-period Spain and Korea have intermediate to high capital stock growth, whilst the USA is a slow grower in this period as well as in the subsequent periods. The growth rate of Korea's capital stock was negatively affected by the outbreak of the Korean war, which causes the stock to fall heavily in 1951-53. Spain remains an intermediate grower in the 1973-80 period to become a slow grower during 1980-89. Korea becomes a very high grower in the 1973-89 period with growth rates far beyond the other countries.

Table 17
INTERNATIONAL COMPARISON: TOTAL GROSS CAPITAL STOCK, 1950-1989
(Annual average compound growth rates)

| | 1950-73 | 1973-80 | 1980-89 |
|---------------------------|-------------|-------------|-------------|
| Argentina | 3.75 | 4.09 | 1.45 |
| Brazil | 8.76 | 10.40 | 5.51 |
| Chile | 2.86 | 2.10 | 2.27 |
| Colombia | 4.00 | 4.79 | 4.58 |
| Mexico | 8.10 | 7.84 | 4.83 |
| Venezuela | 7.44 | 8.05 | 3.09 |
| Arithmetic Average | 5.81 | 6.21 | 3.62 |
| Korea | 5.82 | 15.05 | 11.40 |
| Spain | 6.30 | 6.74 | 3.91 |
| USA | 3.44 | 3.45 | 3.17 |
| Arithmetic Average | 5.19 | 8.41 | 6.16 |

Source: Annex C and D.

Table 18 presents a comparison of gross and net capital-output ratios in specific benchmark years of the 1950-89 period. The USA has an almost constant capital-output ratio whilst all the other countries show rising ratios with the exception of Chile, where capital productivity rose. The initial ratio for Korea in 1950 is misleading because due to heavy war damage of the Korean war this ratio falls down to somewhat over 1 in the next years. The net ratios show almost the same tendency, but are influenced by the process of acceleration and deceleration of capital formation.¹⁸

Table 18

**INTERNATIONAL COMPARISON: GROSS AND NET CAPITAL
OUTPUT RATIOS. 1950-1989**
(in 1980 international dollars)

| Arithmetic Average | 3.1 | 1.7 | 2.8 | 1.9 | 3.7 | 2.5 | 3.9 | 2.4 |

Source: Annex C and D.

In graph 4 we show the growth of GDP per capita of these countries during the 1950-89 period but as the GDP growth performance of the Latin American countries has already been commented above (see Graph 3) we now briefly look at the other countries. The USA experienced low but steady growth during the 1950-89 period. Korea grew very fast during the whole period with the exception of the early fifties and the beginning of the eighties. Spain grew at the same pace as Brazil until the seventies when growth rates fell. Recently Spain has started to grow again.

¹⁸ An interesting case is Spain where in the 1980-89 period the gross capital-output ratio rises while the net ratio fell somewhat. This means that the growth rate of the gross stock was higher than the growth rate of GDP and this last growth rate was higher than the growth of the net stock.

Graph 4
International Comparison: GDP Per Capita
1960-89

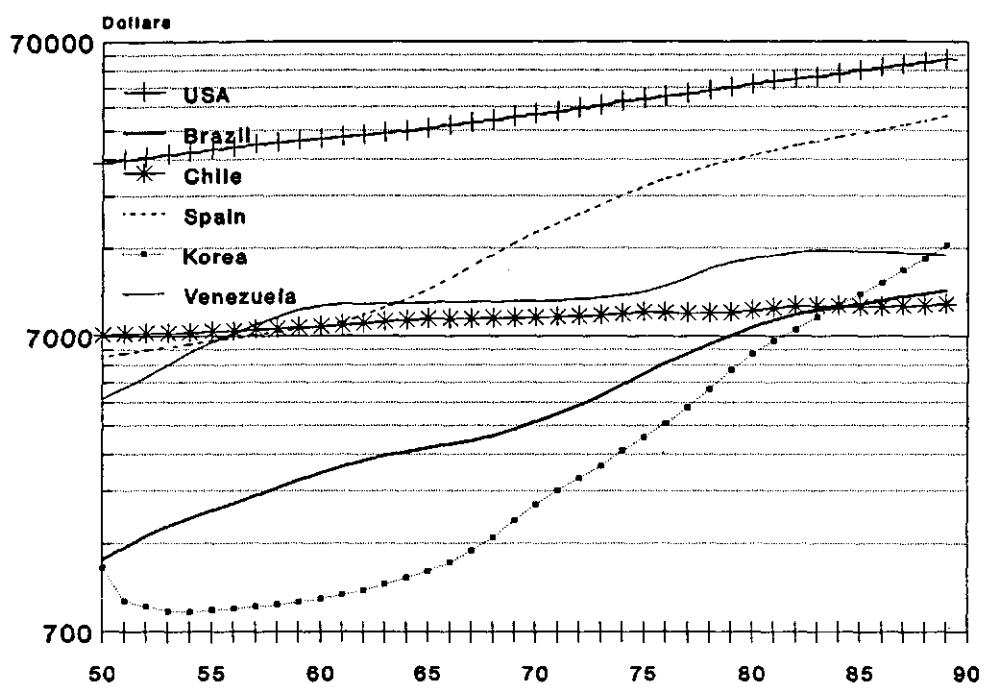

Source: Annex A.

Finally in Graph 5 we show an international comparison of the growth of the gross total fixed capital stock per capita of three Latin American and the three other countries of our sample. This graph together with Graph 1 and 2 for the Latin American countries gives a good impression of the ample spectrum of capital stock growth (and levels) in this group of countries.

Most impressive is the capital stock growth of Korea starting around 1960, but one should also note Venezuelan growth especially during the first part of the period under consideration when starting from almost the same level as Korea (even somewhat lower) it grew at a fast pace and only in the late seventies Korean total capital stock became bigger than the Venezuelan one. If one looks at GDP growth of Venezuela and Korea it shows that already in the late sixties Korea's GDP had become bigger than Venezuela's.

Spain's total capital stock per capita grew at a somewhat low rate until the middle sixties when it settled on a much higher growth path. Chile's total fixed capital stock per capita remained almost the same whilst the USA experienced steady growth during the period.

ANNEX A

GDP, POPULATION AND INVESTMENT: SOURCES AND METHODOLOGY OF ESTIMATION

For all countries we give a detailed description of the sources used for the construction of our series which consist of, GDP, population, total capital formation, capital formation in machinery and equipment and capital formation in residential and non-residential structures. For 1950 onwards, if not otherwise specified, the series used for Latin America are derived from currently collected official estimates by ECLAC corresponding to the most recent revision of the United Nations System of National Accounts (SNA)¹.

This applies especially to GDP and in many cases total capital formation estimates. In the case of disaggregated capital formation often the official series in Latin America only start in the 1970s and for residential capital formation sometimes no official estimates were available.

For years before 1950, the estimates have nearly all been made retrospectively and the underlying data are less complete. Nevertheless, most of the historical estimates are based upon substantial statistical research by distinguished scholars, and in some cases emanate from the governmental statistical service responsible for making the more recent official estimates. But the estimates for the first half of the 20th century are obviously not as comparable as those for 1950 onwards, and in some cases may well be substantially be revised when further research is done. This applies especially for the data before 1925 in the case of disaggregated capital formation. The weakest estimates are for Venezuela before 1937 when practically no information is available and therefore the results for this country should be regarded as tentative.

In order to compare levels of output, capital and income per capita or productivity in different countries it is useful to have a unit which expresses the comparative value of their currencies better than exchange rates. The latter reflect purchasing power over tradeable goods and services, and are subject to a good deal of fluctuations as a result of capital movements.

In this study the results of the United Nations ICP IV were used which generated purchasing power parities (PPP) for GDP and the different types of capital formation. The PPPs were expressed in "international dollars" obtained by applying a common set of prices, representative of the world price structure, to the quantities of the commodities and services entering into each country's final expenditure on GDP. The PPPs for Latin America were provided by Alan Heston of the University of Pennsylvania and former director of the ICP. These PPPs differ somewhat from the ones published in United Nations (1987) which contained some computational errors.

Tables 1-3 show for each Latin American country levels of real GDP each in national currency and "international dollars", population and GDP per capita. The sources for the population estimates are given in the source note below. Tables 2 and 3 give gross total and disaggregated investment in national currencies and as a percentage of GDP.

¹United Nations, A System of National Accounts, Series F, No.2, Rev.3, New York, 1970.

Sources

GDP and Investment

Latin American Countries

Argentina: The source for 1900-1950 including GDP, total fixed capital formation and fixed capital formation in machinery and equipment was, Banco Central de la República Argentina, Cuentas Nacionales, Series Históricas, Volúmen III, Buenos Aires, 1976. Fixed capital formation in residential structures from 1900-1955 from ECLAC, El Desarrollo Económico de la Argentina, Annex, Santiago de Chile, 1958. For 1955-1970 fixed capital formation was estimated at a 46 per cent of fixed capital formation in non-residential structures, which is the average residential/non-residential structures ratio for 1955 and 1970. From 1970-1989, ECLAC estimates based upon official statistics were used.

Brazil: Total GDP from 1900-1920 using the indices from C. Haddad, "Crescimento do produto real brasileiro - 1900/1947", Revista Brasileira de Economia, Vol.29, no.1, jan./mar. 1975, and for 1920-1950, total GDP from R. Zerkowsky and M.A. de Gusmao Veloso, "Seis décadas de economía a través do PIB", Revista Brasileira de Economía, Vol.26, no.3, jul./set., 1982. Total capital formation for 1900-1925 calculated as the sum of capital formation in machinery and equipment and capital formation in residential and non-residential construction. For 1925-1950 ECLAC, Economic Survey 1949, New York, 1951 was used to calculate a capital coefficient as the ratio of capital goods and the sum of agricultural and industrial production with an adjustment for differences in base year. Capital formation in machinery and equipment for 1900-1925, A.V. Villela and W.Suzigan, Brazilian Economic Studies, Government Policy and the Economic Growth of Brazil, 1889-1945, no.3, IPEA/INPES, 1977, table 133, p.363 using a quantum index of industrial capital goods imports, for 1925-1949 from ECLAC, Economic Survey 1949, using index of imports of other capital goods and for 1949-1969, C.G. Langoni, As Causas do Crescimento Econômico do Brasil, APEC, 1974, based upon an unpublished study of Fundação Getulio Vargas, Formação Bruta de Capital, 1970. Capital formation in non-residential structures for 1900-1925 based upon Villela and Suzigan, op.cit., p.359, using a combined quantum index of domestic cement consumption and domestic rolled-steel consumption. Capital formation in residential structures for 1900-1920 from Villela and Suzigan, op.cit., p.359, using a quantum index of domestic cement consumption and 1920-1985 was based upon IBGE, Brasil, Censo Demográfico, 1920, 1940, 1950, 1970, 1980. For the 1985 data the national household survey of IBGE was used. On the basis of the census and household survey information a stock of housing was estimated. Gross investment was calculated on the basis of the yearly increase of the housing stock plus the depreciation. With these data an index of investment in residential structures was calculated with base year 1974. For 1974, J.G. Borges and F.P. Vasconcellos, Habitacão para o Desenvolvimento, Rio de Janeiro, Block Editores, 1974, estimated capital formation in residential structures at 20 per cent of total capital formation. For 1985-1989 capital formation in residential structures was estimated as 39 per cent of capital formation in non-residential structures.

Chile: Total GDP for 1900-1908 from A. Maddison, The World Economy in the 20th Century, OECD, p.125, 1988, and for 1908-25, from M.A. Ballesteros and T.E. Davis, "El crecimiento de la producción y el empleo en sectores básicos de la economía chilena, 1908-1957", Cuadernos de Economía, Universidad Católica de Chile, septiembre-diciembre 1965, for 1925-1940 ECLAC, Economic Survey 1949, New York 1951 and for 1940-1950, ECLAC, Statistical Bulletin for Latin America, Vol.IX, No.1-2, New York, 1972. Total capital formation for 1900-1904 and 1916-1919, estimated at three times capital formation in machinery and equipment and for 1905-1915, estimated at two times capital formation in machinery and equipment. Total capital formation for 1920-1923 estimated at 10 per cent of GDP and for 1924-1925 at 15 per cent of GDP, for 1925-1940 ECLAC, Economic Survey of Latin America 1949, New York, 1951 and for 1940-1950 ECLAC, Statistical Bulletin for Latin America, 1972. Capital formation in machinery and equipment for 1920-1940, using a quantum index of imports of capital goods from ECLAC, Economic Survey of Latin America 1949, New York, 1951 and for 1940-1950, CORFO, Cuentas Nacionales de Chile, 1940-1962, Santiago, 1963. Capital formation in residential structures for 1920-1925, applying the index of total capital formation and for 1925-1928 using the 1928 ratio of capital formation in residential structures to total capital formation. For 1928-1940 ECLAC, Economic Survey of Latin America 1949, New York, 1951, for 1940-1954 CORFO, Cuentas Nacionales de Chile 1940-1954, Santiago, 1957 for 1954-1960, CORFO, Cuentas Nacionales de Chile 1940-1962, Santiago, 1963 for 1960-1975 ODEPLAN, Cuentas Nacionales de Chile 1960-1975, Santiago, 1976. 1974-1982, ECLAC based upon official estimates and for 1982-1989 Banco Central de Chile, Boletín Mensual, Santiago, February 1986 and September 1990.

Colombia: Total GDP for 1900-1925 from A. Maddison, op.cit., using his benchmarks for 1900, 1913 and 1929, and interpolating the years in between and 1925-1950 from ECLAC, Statistical Bulletin for Latin America, Vol.IX, 1972. Total capital formation for 1900-1909 was estimated constant at 10 per cent of GDP and for 1910-1924 at 18 per cent of GDP based upon the periodization and description of W.P. McGreevey, "The Transition to Economic Growth in Colombia" in R. Cortes Conde and S.J. Hunt (eds.), The Latin American Economies, New York, 1985 and for 1925-1950 from ECLAC, Statistical Bulletin for Latin America, Vol.IX, 1972. Capital formation in machinery and equipment for 1900-1925 estimated at 33 per cent of total capital formation and for 1925-1950 from Statistical Annex, to ECLAC, The Economic Development of Colombia, Geneva 1957. Capital formation in residential structures from 1900-1925 estimated at 6 per cent of capital formation in non-residential structures and for 1925-1950 from the Statistical Annex, to ECLAC, The Economic Development of Colombia, Geneva, 1957. For 1950-1970, estimated at 28 per cent of capital formation in non-residential structures.

Mexico: Total GDP for 1900-1950, from Banco de Mexico, Indicadores Económicos, Acervo Histórico V, May 1986. Whereby 1911-1920 was interpolated on the basis of the 1910 and 1921 data. Total capital formation for 1900-1910 and for 1920-1925 was estimated at 10 per cent of GDP. For the period 1911-1920 we have assumed that no capital formation occurred i.e. capital formation in this period was offset by war destruction caused by the mexican revolution. For total capital formation from 1925-1939, ECLAC, Economic Survey of Latin America 1949, New York, 1951, was used to calculate a capital coefficient as the ratio total of available capital goods

(see Table 6, page 414) and national production (Table 3A, page 404) and for 1939-1960 from Banco de Mexico, Indicadores Económicos. Acervo Histórico V, May 1986. Capital formation in machinery and equipment for 1920-1925 applying the ratio of 1925 and for 1925-1939, ECLAC, Economic Survey of Latin America 1949, New York, 1951, based upon imports of other capital goods (see Table 6, p.414). For 1939-1950 from IBRD, The Economic Development of Mexico, Report of the Combined Mexican Working Party, Baltimore, 1953, and for 1950-1960 from Banco de Mexico, Cuentas Nacionales y Acervo de Capital, Consolidadas y por Tipo de Actividad Económica, 1950-1967, junio de 1969. Capital formation in non-residential structures for 1900-1929 assumed to move as total capital formation, for 1929-1970 from INEGI, Estadísticas Históricas de México, 1985 using an index of the total housing stock adjusted for the changing weight of brick houses in total housing stock.

Venezuela: Total GDP for the period 1900-1936 was estimated rather crudely on the basis of an index of population growth (weight 0.6) from CICRED, La Población de Venezuela, 1974 and an index of Venezuela's principal exports (weight 0.4) from C. Quero Morales, Imagen-Objetivo de Venezuela. Reformas Fundamentales para su Desarrollo I, Banco Central de Venezuela, 1978. For 1936-1950 from ECLAC, Series Históricas del Crecimiento de América Latina, Santiago, 1987. Total capital formation was estimated as follows: 1900-1909 at 10 per cent of GDP; 1910-1919 at 15 per cent of GDP; 1920-29 at 20 per cent of GDP and 1930-37 at 15 per cent of GDP on the basis of the description of Venezuela's economic development in C. Quero Morales, op.cit. and F. Brito Figueroa, Historia Económica y Social de Venezuela, Tomo II, Caracas, 1966, which both indicate that the period 1900-1909 was one of stagnation and that during 1910-1919 foreign investment increased especially in the oil sector (63 per cent of total capital formation in industry came from foreign investment, see F. Brito Figueroa, op.cit. p.398) during 1920-1929 Venezuela experienced a period of rapid economic growth whilst in the period 1930-1937 growth was affected by the depression of the 1930s. Total capital formation from 1938-1945 based upon estimates of private investment and government expenditures from Banco Central de Venezuela, Memoria, 1949, 1950 and 1951 and for 1945-1950 from ECLAC, Economic survey of Latin America 1951-1952, New York, 1954. Capital formation in machinery and equipment for 1920-1938 was estimated by applying the ratio capital formation in machinery and equipment to total capital formation found for 1938 and 1938-1950 estimated on the basis of imports of capital goods from Banco Central de Venezuela, Memoria 1949, Caracas, p.82. Capital formation in residential construction for 1900-1936 estimated at 30 per cent of capital formation in construction and for 1936-1950 estimated at 14 per cent of total capital formation. For 1950-1976, from Banco Central de Venezuela, La Economía Venezolana en los Ultimos Treinta y Cinco Años, Caracas, 1978, p.177.

Other Countries

Korea: Total GDP from 1900-1910 from A. Maddison, op.cit., using his benchmarks for 1900 and 1913 to interpolate the 1900-1910 period. Total GDP 1911-1938 from T. Mizoguchi and M. Umemura, Basic Economic Statistics of Former Japanese Colonies 1895-1938, Toyo Keizai Shinposha, Tokyo, 1988, p.238 and was calculated as the average of the Net Domestic Product at factor cost and the Gross Domestic Expenditures at market prices. 1939-1987 from A.

Maddison, op.cit. and the serie was updated to 1989 using IMF, International Financial Statistics, Vol.XLIV, No.2, 1991. Total capital formation from 1911-1938 from T. Mizoguchi and M. Umemura, op.cit., table 8, p.238 and from 1939-44 estimated at 12.9 per cent of GDP, for 1945-1946 and 1951-1952 capital formation was estimated to be zero and for 1947-1950 a 5 per cent of GDP. Capital formation in machinery and equipment and non-residential structures from 1911-1938 from T. Mizoguchi and M. Umemura, op.cit., table 50, p.285. From 1939-52 capital formation in machinery and equipment and non-residential construction estimated at 20 and 50 per cent respectively of total capital formation. Capital formation in residential structures for 1900-1910 estimated and from 1911-1938 and 1939-52 estimated at 25 and 30 per cent of total capital formation respectively. In order to be able to adjust the capital stock for war damage during the Korean war we have used a war damage coefficient of 33 per cent based upon estimates in Encyclopaedia Britannica, Inc., The New Encyclopaedia Britannica, 15th edition, 1974, part 10, History of Korea, p.513. From 1953-1969 all the data for capital formation come from Bank of Korea, National Income in Korea 1975, Seoul, 1975 and from 1970-1989 from Bank of Korea, National Accounts 1990, Seoul, 1990.

Spain: Total GDP for 1920-1954 from J. Alcaide, "La renta nacional 1901-70: una revisión urgente", in Datos Básicos para la Historia Financiera Española 1850-1975, Madrid, Instituto de Estudios Fiscales and 1954-1987 from OECD, National Accounts, various editions. GDP updated to 1989 using IMF, op.cit. Ratio of gross fixed capital formation to GDP for 1920-1953 from A. Carreras, "Gasto Nacional Bruto y Formación de Capital en España, 1849-1958", in P. Martín Aceña and L. Prados de la Escosura, eds., La Nueva Historia Económica en España, Tecnos, Madrid, 1985, p.41-2 and 1954 onwards from OECD, National Accounts, various editions.

USA: The estimates for the USA were kindly provided by Angus Maddison and come from the worksheets of his new book Dynamic Forces in Capitalist Development, Oxford University Press, 1991.

Population

Latin America from 1900-49 from the sources mentioned in Maddison (1989). Venezuela from CICRED, La Población de Venezuela, Caracas, Venezuela. 1950 onwards for all Latin American countries come from CELADE, Boletín Demográfico, Año XXIII, No.45, Santiago, Chile, 1990. Other countries for 1900-1987 from Maddison (1989) updated to 1989 for the USA and Spain with OECD, Main Economic Indicators, Paris, 1991. Korea updated to 1989 with Council for Economic Planning and Development, Taiwan Statistical Data Book 1990, August 1990. For 1900-49 the Maddison (1989) benchmarks; 1900, 1913, 1929, 1938 were used and the years in between directly interpolated, except in the case of Argentina where the yearly estimates for 1913-49 come from IEERAL, "Estadísticas de la evolución económica de Argentina", Estudios, jul./sep., 1986. In the case of Mexico I used INEGI, Estadísticas Históricas de México, Tomo I, Mexico, 1985, for yearly estimates for 1900-10 and 1921 and interpolated these with the benchmarks of Maddison (1989). For 1950-85 CELADE gives 5-yearly estimates which were interpolated and 1986-89 come from yearly estimates of CELADE.

Table 1

ARGENTINA: LEVELS OF REAL GDP, POPULATION AND PER CAPITA GDP, 1900-89.

| Year | GDP in Constant 1980 | | | Population (Thousands) | GDP per Capita | Year | GDP in Constant 1980 | | | Population (Thousands) | GDP per Capita |
|------|--|----------------------|---------------|---------------------------|-------------------|-------------|--|----------------------|---------------|---------------------------|-------------------|
| | National Prices (Million Australes) | Dollars (Million) | International | | | | National Prices (Million Australes) | Dollars (Million) | International | | |
| 1900 | 16,274,530 | 6,008 | 4,693 | 1,280 | 1950 | 107,560,399 | 39,705 | 17,150 | 2,315 | | |

ANNEX D

A SHORT-CUT METHOD FOR CAPITAL ESTIMATION

In the case of Spain it was not possible to use the same methodology as for the other countries because the series of historical capital formation do not go backwards far enough and the level of disaggregation of the available series was not sufficient. In this case we applied an alternative methodology using total capital formation assuming a service life of 30 years, i.e. the capital stock consists of the previous 30 years of total capital formation. This assumption as if all capital goods had the same service life of 30 years is obviously not correct but comes closely to the observed average service life of our group of countries. We have used this methodology for 5 countries of our sample, in order to be able to analyze the sensibility of this method in comparison with the methodology used for the whole group of countries, because it might serve as a short-cut method in the case of many other countries where no sufficient historical data for disaggregated capital formation series are available. The countries included besides Spain were: Brazil, Chile, Korea and the USA.

In this Annex a set of two tables is presented for each of the above mentioned countries containing the gross and net capital stocks, the average ages and the capital-output ratios in constant 1980 national currencies and in constant 1980 dollars respectively.

The following Tables 1 and 2 compare the results of the standard and the short-cut method for the 1950-89 period. It becomes clear from these tables that the results with respect to levels and growth rates of the short-cut method come rather close to those of our standard method. No trend can be discerned showing that one method gives systematically higher or lower results than the other. In the case of the ratio of short-cut to standard method some countries like Brazil have higher and some like Chile have lower capital stock levels. On the average the levels of the short-cut method gross stocks are about 3 per cent higher and those of the net stocks about 2 per cent lower. The growth rates show quite similar results in the two methods with the differences being in almost all cases below a 10 per cent. The biggest differences occur for 1950 in the cases of Brasil and Korea were the short-cut method gives much higher estimates (over 20 percent).

The differences between the estimates on the basis of national currencies are not very different from the ones in international dollars and the changes are caused by the changes in the composition of the capital stocks when applying the disaggregated capital formation PPP's and the PPP for total capital formation in the case of the short-cut method. The growth rates of the short-cut method are obviously the same in national currencies and international dollars because of the fact that only one PPP is used.
