## I. INTRODUCTION AND SUMMARY

At this moment in time there is an awareness that the persistent economic crisis affecting Latin America and Caribbean countries has had a high social cost shown by the severe deterioration in the standard of living of broad social sectors and, particularly, an increase in unsatisfied basic needs in poorer social strata (G.A. Cornia, 1987; PREALC, 1988b; ECLAC, 1987). This report is an effort to bring together and update some of the fragmentary and dispersed data existing in the region on this subject. It also attempts a general analysis of the dynamics of this deterioration. It is not, therefore, an "assessment" of the social situation --not everything has deteriorated since in many countries there have also been improvements in some areas-- but a warning and a step towards defining those areas and negative social tendencies which should draw the attention of government planners and action in coming years.\*/

On the whole, it suggests that there seems to have been a rupture in the social and economic development style which predominated in the region before 1982 (ECLAC, 1989). In the majority of the countries, there can already be seen what could be a new way of functioning of the economy which exacerbates some distortions of the previous model --such as productive heterogeneity-- and to which new distortions are added --such as the already chronic shortage of capital, a virtual stagnation in the creation of highly productive jobs and a reduction in per capita public social spending. The social cost of the economic crisis has been greater or less and more or less equitably distributed in each country according to a complex causality which combines the seriousness of the economic retrogression, the policies applied to meet it, the growth rate of the population, the present stage of development of each country, the degree of democratic participation, and the strength of community and trade-union organizations. In almost all the countries, however, the new dynamics mentioned present a strong challenge to social policy in the 1990s; there is a real danger that the slow social progress achieved before could stagnate and the vicious circle of social problems which feeds itself could broaden. Particularly worrying is the increase in the number of young adults without sufficient access to education and productive employment, who are excluded from productive modernization, both in the countries of the region where the most rapid phase of development has been recent, now the majority, and in the less developed countries which have not yet taken off.

---

\*/ The implications of these negative social trends must be taken into account in the formulation of crime prevention policies. This theme will be analysed in a document prepared for this meeting by the United Nations Latin American Institute for Crime Prevention and the Treatment of Offenders.

## II. MAIN REPERCUSSIONS ON SOCIAL DEVELOPMENT OF THE ECONOMIC CRISIS

It is not the purpose of this paper to repeat the analysis of the "debt crisis" or of the economic growth problems presently confronting the region (ECLAC, 1988a). It is absolutely necessary, however, to stress some changes in economic trends which are central to the dynamics of the social deterioration analysed below.

The first of these economic changes is the negative flow of capital (see figure 1) which appeared for the first time in the region in 1982 as a result of the increase in foreign debt service, the pronounced drop in new loans and investments, and unfavourable market conditions for many of the region's exports. The result has been a net transfer of resources from the region to developed countries which, far from being conjunctural and limited to 1982, has been similar or greater in each following year (see figure 1). The persistence of this net transfer of resources and the difficulties for saving and investing this imposes, contribute to a notorious and equally persistent drop in historical rates of product growth (see figure 2) and, given demographic growth, in the value of the per capita gross domestic product in almost all the countries of the region. In fact, only Colombia and Cuba showed significant per capita GDP growth between 1982 and 1988. Starting in 1984, the GDP has grown significantly in Chile (see figure 3 and table 1 of annex 1), while in the other countries, in Argentina, Bolivia, El Salvador, Guatemala, Guyana, Haiti, Honduras, Nicaragua, Mexico, Peru, Trinidad and Tobago, Venezuela, and (in 1988) Panama, this key indicator stagnated or fell more than 10% and up to 39% in the last seven years. Inevitably, these retrogressions in economic growth and investment capacity have had negative effects on employment, income, and spending on social services and human resource training.

### III. EMPLOYMENT AND INCOME IN THE CRISIS

#### 1. Open unemployment

One of the most immediate and dramatic social effects of the foreign debt crisis was the strong increase in open unemployment in several of the countries of the region such as Bolivia, Colombia, Costa Rica, Chile, Guatemala, Paraguay, Peru, Uruguay and Venezuela (see table 2 of annex 1).

However, except in five countries (Argentina, Bolivia, Ecuador, Honduras and Panama), open unemployment in Latin America had shown a general tendency in recent years to stabilize at historical levels (see figure 4). On the other hand, the social cost to labour of the economic crisis seems increasingly more apparent in other aspects, which already threaten to become chronic problems: the stagnation of employment in the modern sector, the low participation of wages in the national product, and the absorption of the work force in "residual" sectors of low income employment --that is, in less productive jobs within the informal urban sector and, to a lesser degree, in agriculture (see tables 1 and 2).

#### 2. Recent change in employment structure

In the 1960s and 1970s, the sustained economic growth of the majority of Latin American and Caribbean countries was accompanied by a growing absorption into the modern sector of increasingly better qualified and more productive human resources, while unqualified labour in agriculture was rapidly diminishing as a proportion of the economically active population. This "structural occupational mobility" (ECLAC, 1989), although insufficient to reduce the relative size of the informal urban sector or the absolute number of poor persons, brought with it a growing number of relatively well-paid jobs in the formal sector, especially salaried posts in large and medium-sized private enterprises and in the public sector. But during 1980-1987 this positive dynamic was reversed in many countries and became negative.

In the first place, the creation of new posts in large private enterprises (on average, the most productive and better paid) has been practically stagnant for seven years in five of the seven countries where PREALC has been able to provide detailed data (see table 3). Stagnation in absolute numbers can be seen in Argentina, Brazil, Costa Rica, Colombia and Mexico. Only Chile (where there has also been a transfer of large State enterprises to the private sector and high unemployment) and Venezuela showed growth rates in employment in large private enterprises, barely equivalent to the growth rates of the total economically active population (see tables 3 to 9 of annex 1).

LATIN AMERICA: INDEXES OF ABSOLUTE GROWTH OF THE ECONOMICALLY  
ACTIVE POPULATION BETWEEN 1980 AND 1987

	Economically active population (1980=100)	Population employed in the informal urban sector (1980=100)	Population employed in large private enterprises (1980=100)
Argentina	111	118	103
Chile	120	109	123
Brazil	129	170	102
Costa Rica	124	127	107
Colombia	123	148	105
Mexico	125	182	99
Venezuela	125	118	122

Source: ECLAC, on the basis of information provided by PREALC from official sources and household surveys.

Meanwhile, the economically active population has shown steadily increased, although at highly varied rates according to the current demographic transition stages of the various countries in 1980-1987.

There have been two more general consequences of both phenomena. The first is a notable reversal from the historical decrease in the proportion of the population working in agriculture (see table 2), to an accumulated growth of almost 13% in seven years. The second consequence has been a staggering growth of the informal urban sector in many countries of the region. In Colombia this was 48% greater in 1987 than in 1980; in Brazil its growth was 70% and in Mexico 82%, according to PREALC data.

As a result, the informal urban sector (including self-employed non-professional workers or workers in non-agricultural private enterprises with fewer than 10 salaried employees) is estimated to be the segment which most increased its relative weight in the non-agricultural economic active population between 1980 and 1987 in all of the countries for which there is information (see tables 3 to 9 of annex 1). This situation is in contrast with the previous historical trend in the three decades previous to the crisis when the informal urban sector remained a constant proportion of the non-agricultural economically active population (García and Tokman, 1985). The inversion of the relative weight of formal and informal segments in non-agricultural employment and the growing difference separating them can also be seen in figure 1 of annex 2. As shown in the last tables mentioned, the remaining sector of the economically active population —the public sector— shows different trends according to the intensity of privatization policy in each country, but in no case recovers the role of massive generation of qualified employment which the public sector played in previous years.

### 3. Impacts on income

As a first approximation for understanding the impact of the crisis on income, the data collected by ECLAC (ECLAC, 1988a) indicate that both the minimum wage and average wages have developed very distinctly in the different countries and, in some cases, by 1988 would appear to have recovered their real value of eight years ago (see tables 10 and 11 of annex 1). However, some caution is necessary in interpreting these data. On the one hand, the minimum wage is a legal norm which may or may not correspond to wages actually paid. Also, because of the very high inflation rates in some countries (see table 12 of annex 1) salary and wage adjustments have been insufficient to maintain their real value, with few exceptions. On the other hand, the "average wage" mentioned refers almost exclusively to the industrial sector which both has the greatest trade-union negotiating capacity and least absorbs labour these years.

Data from household surveys provide a view more consistent with the trends observed in the economies of the region and in their labour markets. Actually, between 1980 and 1987, the industrial wage is the only wage which shows a slightly more favourable evolution than the per capita gross national income (see figure 2 of annex 2). Particularly notable is the drop in wages in construction, gateway to the modern sector for less qualified labourers.

A net effect is that total income from labour has grown less than total gross national income since 1983 (see figure 3 of annex 2). Another is that, in seven countries representing more than 80% of the regional population, taken as a whole, the average income from labour dropped strongly in all segments of the economically active population (see table 4). It increased only in Colombia (where there was growth in total product) and in Costa Rica (apparently due to trade-union participation in agreeing to a more equitable strategy for meeting the crisis).

As stated in the PREALC study, "... the way the region adjusted to the external problem of this decade was to compress wage levels more than was necessary to exactly compensate the drop in per capita national income ... It seems reasonable to think that these effects were not entirely inevitable ..." (PREALC, 1988a, pp. 25 and 32).

#### 4. Income in the informal urban sector

Recent studies (Klein, 1988, ECLAC, 1988b) have emphasized the heterogeneous character of the quality of the self-employed manual jobs and the jobs in small enterprises. A significant subsegment of this statistical set, commonly used as a proxy/variable for the informal urban sector, shows a capacity to provide productive employment. However, probably the great growth of jobs in the informal sector has concentrated in "low income and productivity" jobs, jobs created by those who do them, disguised unemployment, or in small enterprises whose owners have taken advantage of the drop in the cost of labour by adopting relationships which more intensively use labour, frequently outside labour protection laws and social security. In fact, the average income in the informal sector dropped by more than 40% in seven years (see table 4).

Table 4

INCOME FROM WORK BY GROWTH <sup>a/</sup>

(Indexes 1980=100 and growth rates)

	1980	1981	1982	1983	1984	1985	1986	1987	Average annual rate	Cumulative change 1980-1987
EVOLUTION OF AVERAGE LABOUR INCOME										
From agricultural employment	100	100.5	93.6	88.8	87.1	78.5	93.8	77.2	-3.6	-22.8
From private formal sector employment, large enterprises	100	98.4	99.8	90.4	90.1	93.4	95.5	85.1	-2.3	-14.9

#### IV. GOVERNMENT SOCIAL SPENDING: EQUITY AND HUMAN RESOURCE CREATION

State spending on health, education, nutrition, housing, social security, etc., serves two general functions in overall social policy. In the short term, it redistributes income from taxes, contributions, and loans paid by society as a whole in the form of benefits or "social consumption" which supplement monetary income and compensate its inequitable distribution. In the medium term, it raises the quality of the human resources of a country both by progressively improving the productivity of the labour force and by providing more personal capital, in the form of knowledge, to social sectors previously left behind.

This last aspect will be treated in section VI on possible future dynamics of social change. The first aspect, on the other hand, belongs to the evaluation of the income and consumption situation of the poorer social strata.

On the one hand, the trends vary considerably from one country to another with respect to relative social spending considered as a proportion of gross domestic product or total government spending (see tables 13 and 17 of annex 1). However, about half of the cases have shown a deterioration in one or both of these indicators for one or more social services, a trend which was not very frequently sustained before the crisis. If we take into account that both product and government spending have fallen in almost all cases while total population continues increasing, probably per capita social spending in real values has fallen absolutely in the majority of the countries. Evidently, this aggravates even more the panorama of the drop in monetary and non-monetary income of the majority, in its standard of living and in its ability to satisfy basic needs. The long-term repercussions are equally evident and especially negative for the evolution of human resources and in relation to the dynamic of social deterioration. In education, particularly, the prolonging of restrictive government policies which were supposed to be short term has already had an influence in the omission of some absolutely necessary investments. "It is different to claim that over a period of one or two years new investments cannot be made" in the educational sector, from following "a non-investment policy in educational services or other social sectors over a long period" (Lagos, 1988, p. 57). In some countries an increase in the number of pupils per teacher has already been noted (see table 18 of annex 1) as well as a tendency suggesting a growing dichotomization of the social structure: an increase in attendance at private educational institutions of children from families which can pay (see table 19 of annex 1).

These data are still too fragmentary to permit speaking with certainty of a clear trend. Indications in some countries of a deterioration in social services is a concern, however, although others seem to have been more successful in public response to present social needs.

## V. RECENT TREND OF SOME WELFARE INDICATORS

The secular improvement of the main aggregate welfare indicators such as the rate of infant mortality or the mortality rate for children under five years of age is not immediately affected by fluctuations in the economic growth rate (see figure 4 of annex 2). These indicators are associated with other variables such as the dissemination of existing medical technology, the provision of State services, the increase in educational levels, the extension of communications, water and sewage infrastructure, etc., which have diffuse positive effects in improving gradually, but persistently, the basic conditions of mortality, sickness, and life expectancy and their delayed effects have a strong positive inertia.

However, with pronounced and very prolonged decreases in monetary and social income, even the semi-autonomous improvement processes inevitably lose momentum compared with the speed of progress before the crisis. This is logically predictable, particularly among the higher risk groups and social sectors which are the most affected by the reduction in productive employment, the drop in real wages, and the reduction in public social services with respect to growing needs. In fact, there has been no delay in the appearance of some indications of a drop in the rate of improvement of infant mortality rates (see figures 5 and 6 of annex 2) which are alarming even though they refer to specific populations. This is true above all when the deterioration happens in countries where these rates are still relatively high and it could have been expected that they would continue to decline even in situations of economic stagnation.

There is also fragmentary, but eloquent, evidence relative to the most direct causes of the lack of improvement in infant mortality rates. Not only have the indicators of maternal-child care begun to fall again, but also in some countries and metropolitan areas, the indicators of child malnutrition, of underweight pregnancies, and underweight births have worsened or stagnated (Patiño et al., 1988; Macedo, 1987), all of which have obvious causal relationships with the danger of child death and are also a logical result of the deterioration of real income in low-income groups.

## VI. THE DYNAMICS OF SOCIAL DETERIORATION: THE CHALLENGE FOR SOCIAL PLANNING

### 1. A wicked example

It is undoubtedly evident that the economic, political and social processes summarized here are closely interrelated. Simply put, the net loss of capital (among other factors) brakes economic growth and the creation of productive jobs; this leads to an oversupply of labour which, combined with austerity adjustment policies and measures to increase earnings from exports leads (especially with inflation) to a reduction in the real income of the poorer levels which is exacerbated by the reduction of governmental redistributive spending on social services. The final effect is of a persistent braking of the progress achieved by the basic social welfare indicators in the period before the crisis. The fact that the social cost has not only not been equitably distributed but, in many countries, has, to the contrary, fallen disproportionately on the less influential majority, carries the serious risk of an increase in social conflicts, a situation which has already actually been seen in more than one country.

### 2. Economic prospects for the nineties

What are the prospects of aggravating or alleviating this negative dynamic? On the one hand, at the moment there is cautious optimism concerning the possibility of diminishing the net capital transfer from the region to the industrialized countries in a few more years (see figure 1) by changing the financial negotiation of the debt to an international political negotiation. Also, there are proposals and experiences of new growth impulses and new stimuli for economic competitiveness, at least in the countries of the region with greater productive potential. However, there is still no forecast of a return of the strong positive flows of capital which helped to feed product growth in the sixties and seventies. To the extent that the recovery of competitiveness rests exclusively on the sectors of greater productivity the present inequity could be maintained or increased even with economic growth.

It is known that before the crisis the concentration of income in many countries of the region was already very high with respect to other regions. The key difference from the present situation is that, before, growth allowed an absolute increase in the income of the lower levels while the expansion of jobs in the modern sector and the educational boom supported an expectation of rising social mobility for the poor (ECLAC, 1989).

These positive circumstances, which gave a degree of legitimacy to the style of development and made inequity more tolerable, are absent from both the present situation and medium-term possibilities.

### 3. Human resources and social mobility: changes in the educational and occupational situation of young adults

One of the relatively more precise methods for detecting the direction of medium-term changes in the socio-occupational structure is to examine the changes and recent situation of young adults (between 15 and 24 years of age). More than a simple evaluation of the present problems of youth or a projection of the human resources available to the economy, the purpose of the exercise rests on the possibility of analysing these human resources as holders of valuable personal capital, whose hopes for incorporation and mobility in productive employment over their future adult working cycles will be determined by a given range of employment opportunities.

Thus, in the sixties and seventies, the tendency for school attendance at secondary and higher levels to increase contributed directly to raising the average productivity of the work force, which found a dynamic demand for qualified labour, especially in modern non-manual services. This improvement of the educational level of successive new generations constituted one of the most important social advances of the decades prior to the crisis. Presently, one of the most worrying aspects of the drop in household income is the danger that youth from families which cannot continue to pay the cost (and the opportunity cost) of their studies will prematurely leave school. Data for recent years on school attendance rates, although they do not allow a detailed analysis, suggest important differences in the level and trend of the proportion of children and youth studying in different countries. In some, there are indications that, in recent years, the historical trend towards better educational coverage could be slowing down (see tables 20 to 24 of annex 1).

In the medium and long term, the probable consequence of today's adolescents prematurely leaving school is the creation of a growing mass of low-qualified workers competing for an always relatively decreasing number of productive manual jobs. Youths without secondary education are virtually condemned (since the great majority will not be able to return to school) to an adult life without socio-occupational mobility, since it has been shown that such a low level of qualification usually limits work prospects to alternatives such as cleaner, loader, street-seller, domestic servant, etc. (Martínez, 1985).

Before the crisis the following secular trend was typical of the socio-productive modernization process in almost all the countries of the region: increases, both among men and women, of the percentage of youth and young adults pursuing formal studies. However, preliminary data taken from household surveys suggests that, since the crisis, the percentage of young men studying has dropped at the secondary school level (15-19 age group) in some countries of the region.

Premature school-learning seems to coincide with a greater tendency for youth to seek paid work. Between 1970 and 1980, in the countries in process of social modernization, labour participation of young men tendend to decrease as their education was prolonged while young women, abandoning exclusive dedication to the home, increased both their educational attendance

and their participation in the labour force (ECLAC, 1989). In the period after the crisis, in contrast, labour participation of young men seems to have increased again in some countries as compared with the overall tendency of the adult population which does not seem to have changed (PREALC, 1988, pp. 45-47).

At the same time as more youth seek work, they are the last to be hired and the first to be fired. In fact, the unemployment rate of the 15 to 19 age group in the crisis period doubled, tripled and reached up to six times the unemployment rate of active persons of about 40 years of age (see table 25 of annex 1). The doubt arising now is whether these youths (who in 1995 will be between 24 and 33) will manage to lower their unemployment rates in the future to the same levels as their seniors now or whether the development style emerging in the region is generating a growing population of unemployables. A different social problem is presented by the growing number of youth with higher education who cannot find suitable employment because of the above-mentioned stagnation in the formal sector. Although in the long term their prospects are less serious than those of the "unemployables" with little education, in the short and medium term the unemployed youths with higher education harbour strong frustration of their expectations based on the traditional role of secondary and higher education as a vehicle for rising social mobility.

#### 4. The challenge and the independent variable

Although the fragmentary information available on education and employment is still inadequate for definitive conclusions, the mere fact that in many countries long-term progress seems to be slowing down, constitutes a relative worsening considering, above all, the strong present and future growth in the number of youths (see table 26 of annex 1). In various countries of the region, a challenge can be seen for the medium term in the form of the rapid growth of a subsector of adult society, uneducated and difficult to employ in the technified economy of the nineties. One should be aware of the possible social dynamics which could create in the region countries increasingly more dichotomized, inequitable, and where open social conflict is becoming a daily emergency.

The independent (or semi-independent) variable is public policy both in the immediate sense (such as alleviating the shortages and problems created by the style) and strategic (such as breaking the vicious circle of poverty reproduction through a multisectoral attack), and in the wider sense, such as creating development styles which increase equity, through a national project which brings together all the instruments of economic planning with the social instruments and which manages to mobilize the civic support of the majority.

Both the problems and the solutions they require are very distinct from one kind of country to another. At a more abstract level, social dynamics in a country where the educational level of youths is relatively high, but the creation of new productive jobs is slow for structural reasons (premature exhaustion of the rapid phase of productive modernization), is different from that of a country where the number of youths grows appreciably from year to

year, with a high percentage under-educated, but where the potential for productive modernization is greater, given its low initial level. Both need to find new sources of dynamism in the creation of productive employment and in the training of human resources to the level of technological change. However, particularly in the second case, a strategy satisfying the criteria of real development—that is, the conditions for increasing equity and progressively eliminating poverty and exclusion—will be more radically different from past styles, from the style imposed by the crisis, and from the orthodox formulas for imitative growth. To achieve this general purpose, and to design the three types of social planning enumerated above, it is absolutely necessary to carry out more empirical research on the various facets of the possible dynamics of social deterioration which this paper has tried to point out.

In conclusion, an analysis of the preliminary data suggests that the present economic crisis has social repercussions which go beyond the immediate present deterioration observed in the welfare level of large sectors of the population of the countries of Latin America and the Caribbean. Prospects for the 1990s of predictable rates of economic growth, the creation of new productive jobs, and government resources suggest that a new social dynamic may arise lacking various processes of social progress which characterized the periods of rapid development, the sixties and seventies. Although the seriousness of the dynamics of deterioration or social stagnation will be more or less accentuated according to the particular characteristics of each country, an increase in social problems (especially those affecting the new generation of young adults who cannot realize their aspirations for occupational mobility through education and the rapid creation of new jobs in the modern sector) will be a challenge which social policy, in its overall formulation and in its various subsectors, will probably have to meet in the 1990s.

Source: ECLAC, *Preliminary overview of the Latin American economy*, (LC/G.1536), Santiago, Chile, 1988, page 18.

<sup>a</sup>National urban rate, average for April-October. 1986: October, 1988: May. <sup>b</sup>Whole country, official estimates. The figures are not strictly comparable over time because the geographical coverage of the surveys has been expanding of year by year. <sup>c</sup>Metropolitan Areas of Rio de Janeiro, São Paulo, Belo Horizonte, Porto Alegre, Salvador and Recife, average for 12 months; 1980, average June-December; 1988, average January-September. <sup>d</sup>Bogotá, Barranquilla, Medellín and Cali, average for March, June, September and December; 1985: average for March, July and December; 1986: average for April, June, September and December; 1988: average for March, June and September. <sup>e</sup>National urban. Average for March, July and November; 1984, average March and November; 1986: average March and July; 1987: July. As from the latter data, the figures are not strictly comparable with the preceding ones as they correspond to the new Multi-Purpose Household Survey, in which there have been changes in the methodology. <sup>f</sup>Greater Santiago. Average for four quarters. As from August 1983 data relate to the Metropolitan Region of Santiago. Since October 1985 the figures are not strictly comparable with the preceding ones due to changes in the design and size of the sample. <sup>g</sup>Whole country. Official estimates. <sup>h</sup>Whole country, official estimates; 1986: Urban Labour Force Survey; 1987: March, Central District. <sup>i</sup>National average, April and October. <sup>j</sup>Metropolitan areas of Mexico City, Guadalajara and Montetrey, average for four quarters; 1988: average January-September. <sup>k</sup>National urban, August of each year. From 1978 refer to Metropolitan Region. 1980: data from population census of that year. <sup>l</sup>Asunción, Fernando de la Mora, Lambaré and urban areas of Luque and San Lorenzo, annual averages; 1981: first half of year; 1983: average for September, October and November; 1984: average for August, September and October; 1985: average for November and December. <sup>m</sup>Metropolitan Lima; 1985: official estimates. <sup>n</sup>Montevideo, average of four quarters. 1988: average of two quarters. <sup>o</sup>Country-wide urban rate, average for the two half-years; 1984 and 1985, country-wide rate; 1986: second half of year; 1988: first half of year.

<sup>a</sup> Preliminary figures.

<sup>b</sup> Average total monthly wages in manufacturing. Average for twelve months. 1988, average January-September.

<sup>c</sup> Average wages in basic industry, deflated by the CPI for Rio de Janeiro. Average for twelve months. 1988, average January-May.

<sup>d</sup> Average wages in manufacturing in the State of São Paulo, deflated by the cost-of-living index for the city of São Paulo. Average for twelve months. 1988, average January-September.

<sup>e</sup> Wages of Manual workers in manufacturing (except coffee processing). Average for twelve months. 1988, average January-July.

<sup>f</sup> Average wages declared for social security members.

<sup>g</sup> Average remuneration of wage-earners in non-agricultural sectors. Average for twelve months. 1988, average January-October.

<sup>h</sup> Average wages in manufacturing. Average for twelve months.

<sup>i</sup> Wages of private-sector workers in Metropolitan Lima. Average for February, May, August and November. 1987, average for twelve months. 1988, January-October.

<sup>j</sup> Index of average real wages. Average for twelve months. 1988, average January-September.

<sup>k</sup> Compared with the same period in the previous year.
