Workshop on Agricultural Research Policy
and Management in the Caribbean
Port of Spain, Trinidad
26-30 September 1983

AGRICULTURAL RESEARCH MANAGEMENT
Prepared by
John L. Nickel
Director General, Centro Internacional de Agricultura Tropical (CIAT)

Organized jointly by the United Nations Economic Commission for Latin America (UNECLA) Subregional Headquarters for the Caribbean and the Caribbean Council for Science and Technology (CCST) with support from the International Service for National Agricultural Research (ISNAR), the Swedish Agency for Research Co-operation with Developing Countries (SAREC), the International Development and Research Centre (IDRC), the Commonwealth Foundation, the University of the West Indies (UWI) and the Government of Trinidad and Tobago.

UNITED NATIONS
ECONOMIC COMMISSION FOR LATIN AMERICA Office for the Caribbean
AGRICULTURAL RESEARCH MANAGEMENT
Prepared by
John L. Nickel
Director General, Centro Internacional de Agricultura Tropical (CIAT), Cali, Colombia

It is an honor for me to address this distinguished group on the important subject of agricultural research management. The need for well-managed agricultural research institutions has never been greater, especially in tropical developing countries where new agricultural technology is urgently required to reverse the current trends that show these countries becoming increasingly dependent on food imports. Fortunately, national governments and international financial institutions are recognizing the key role of agricultural research and more amounts of funds are becoming available to build, develop and strengthen national research institutions in the third world. This workshop on agricultural research policy and management in the Caribbean, therefore, is very timely and the topic most relevant.

All of us who manage research institutions are aware of funding constraints and convinced that if we had more funds for our particular institution we could accomplish more. No doubt that is true. Nevertheless, the topic of how to obtain more funds will be conspicuous by its absence in this paper. I am convinced that the key constraint for more effective agricultural research in many institutions today is management; until management is improved, additional resources will not be used effectively.

The topic assigned to me, agricultural research management, is an extremely broad one. Viewed from the perspective of the management of a national agricultural research system, this subject would encompass definition of national agricultural research goals and priorities; the formulation of a detailed plan of research programs and projects in the framework of a national agricultural research strategy; assignment of responsibilities between various institutions to carry out these programs and projects; allocation of necessary financial, personnel and physical resources to the respective institutions; submission of the resulting plan and budget to appropriate policy working bodies;
implementation of the approved research program; periodic evaluation of results and revision of the strategy and plans; dissemination of the results to the users; obtaining feedback on the impact, strengths and weaknesses of the new technology and incorporating this information into the technology generation process; and, last, but not least, keeping key policy-makers informed on agricultural research achievements.

Obviously, all of these important components cannot be discussed within the scope of a single paper. I assume that the important subjects of developing national science and agricultural research policies, allocating of resources, and integrating the various elements, such as research institutions and universities, into national scientific and development programs will be dealt with elsewhere in this conference. I shall therefore restrict my comments to a consideration of the practical aspects of managing a major agricultural research institution, once the role of such an institution within the national, regional or international framework has been determined and the resources allocated to it.

Many aspects of managing an agricultural research institution are sufficiently similar to the management of any organization so that the principles of management which have evolved over the years, and about which many books and articles have been written, provide useful guidance. The problem is that most agricultural research managers are scientists who suddenly find themselves in an administrative role without the necessary intervening formal training or opportunity to study management principles. Managing scientific research in general, and agricultural research in particular, is sufficiently different from managing other types of enterprises so that special management skills and considerations are indicated.

The need for special management considerations in scientific research organizations stems chiefly from the nature of the personnel involved. Not only are scientists highly educated, but also they are engaged in work that emphasizes independence of thought. Thus, even in large corporations, where general management techniques are usually well understood and employed, it is recognized that these people require unique management skills, and a considerable body of literature on industrial R+D has developed.
Within the overall category of scientific research, agricultural research has some unique characteristics. Pierre described some of the peculiar characteristics of agricultural research, which include dependence on a wide range of scientific disciplines; susceptibility to highly variable environmental conditions; an international character; and the problem of farmers' acceptance of the end results. The complex nature of agricultural research can be understood by thinking of it as a two-dimensional grid: one dimension covering a spectrum of disciplines from the physical sciences through biology and engineering to the economic and social sciences, and the other dimension a spectrum ranging from basic research on the one hand to developmental and technological research on the other.

I will now turn to a consideration of some aspects of the management of an agricultural research institute and the research it conducts.

MANAGEMENT OF THE INSTITUTION

Organization

Traditionally, agricultural research institutions have been organized along disciplinary department lines. More recently, some organizations have created departments based on lines of production. Frequently these two types of organizations are superimposed in a matrix, or multiple command organization.

Matrix management is particularly appropriate when scientists representing different bodies of knowledge and distinct approaches must work together to solve problems, and when expensive resources must be

Matrix management models can be differentiated into two types: the leadership matrix and the coordination matrix. In the former, the project leader motivates the team to work for project goals, whereas in the latter, the coordinator merely keeps everyone informed about the project status and when their contributions will be needed. Multidisciplinary projects following the coordination matrix model are appropriate for universities in which strong, departmental lines are sharply drawn and individual scientists are more dependent on peer approval and publication within their own disciplines. In a problem-solving, production-oriented research organization, however, an interdisciplinary leadership matrix is more appropriate.

In terms of the need for scientists from specialized disciplines to work together to develop and evaluate new technology, and eventually make sure it gets to the consumer, agricultural research bears many similarities to pharmaceutical research and development. Thus the experience of the UpJohn Corporation in converting from a coordination to a leadership matrix is highly relevant. Stucki has described this process and reported that conflict resolution was much better under the latter than in the former organization and cited preliminary evidence of increased productivity under the new scheme.

Merely placing a breeder, a pathologist and an economist together in the same team does not automatically insure interdisciplinarity. Without some "organizational coercion", the individual scientists may continue to think and work within their own disciplines and remain multidisciplinary. In my opinion, in many agricultural research institutions such organizational coercion can best be accomplished by eliminating the matrix and organizing the research scientists

---

into interdisciplinary programs along commodity lines. I have managed all three types: i.e. a coordination matrix in a university context; a leadership matrix, with the "woof and warp" cross hatching of disciplinary departments and commodity-oriented programs; and, more recently, an interdisciplinary organization in which all scientists are assigned to one commodity program or another. Each type of organization has its place, depending on the kind of institution being managed and the amount of financial and manpower resources available in relation to the commodity areas which must be covered. However, the simplicity of the chain of command and the loyalty and motivation that come from building an effective team effort around a single commodity or set of related commodities give this type of organization great advantage when it can be achieved.

Probably the most important ingredient toward making an interdisciplinary team work together effectively is the team leader. Such leadership requires special, rare skills, so the program leaders must be selected with extra care. National research institutions usually bear responsibility for a large number of commodities. Therefore, individual species commodity programs, except for the most important crops and animal species, may not be possible; instead, the organization of programs around groups of related commodities, i.e. grain legumes, root and tuber crops, ruminant animals, etc., may be necessary.

Another resource-related problem is that even in a large organization with few commodities to cover, it may not be possible to assign scientists in highly specialized disciplines to each program on a full-time basis. A useful compromise is to organize most of the institution along interdisciplinary, commodity program lines and to conduct the more specialized research within a scientific support unit serving all programs. The need to share expensive facilities as well as the desirability for close collaboration and communication between scientists within the same discipline can be satisfactorily handled by physically grouping together the labs and offices of scientists who are in the same discipline, but who are assigned to two different commodity programs.

Regardless of the organizational structure employed, strong support units, e.g. biometrics, laboratory services, greenhouses and experiment station facilities, are essential. These should be organized into
service units providing support for all programs.

**Research Institution Administration**

**Role of Administration**

An effective and efficient administration component is absolutely essential to a research institution. Without adequate administrative services, such as accounting, personnel, maintenance, supplies, etc., a research institution cannot function. Nevertheless, the raison d'être of the institution, and the service nature of the administrative units, must never be forgotten.

Arnon\(^8/\) referred to the problems that can be created "if the people engaged in administration come to consider administration as an end in itself and not as a means of furthering research, which is the basic justification for the work of all the people in the organization". Similarly, Pierre\(^1/\) emphasized that "administration should be used to facilitate rather than control research". I frequently remind my colleagues in administration that our role is to facilitate the work of the scientists. This is not to say that the administrative unit staff should not be given important status and treated with full respect as essential partners in an important task. However, non-scientific personnel must always recognize that only the scientists produce new technology; the role of everyone else, including the head of the institution, is only to create the conditions in which this can be achieved most effectively.

Arnon\(^8/\) also pointed out that people trained exclusively in general management without a research background do not understand the potentialities of research, the idiosyncrasies of the researchers, or how research has to be carried out. He and Moseman\(^9/\) both recommended strongly that the head of a research institution should himself be a trained scientist and that the administrative functions should be handled by skilled management personnel; that the administrator of any institution should be a staff officer to the scientist director, acting only after due consultation with him. My own experiences support this view.

---

Administrative Procedures

While I firmly believe that the head of a research institution should be an experienced scientist, the implementation of these principles introduces a built-in weakness which probably represents one of the largest problems in many research institutions today. Scientists undertaking the duties of director of a research organization often do not even realize how ignorant they are of the basic principles of management. Research directors tend to concentrate on program development and neglect the establishment of sound administrative procedures. Among administrative procedures, none are more important than those related to fiscal management. Thus research directors must depend on and give considerable authority to well-trained and experienced financial specialists and see to it that all the instruments for proper budgetary control and internal and external audit procedures are in place to ensure fiscal integrity and a high level of cost consciousness while, at the same time, avoiding excessive bureaucracy.

In the enforcement of administrative procedures, high degrees of fairness, integrity and flexibility are essential. These cannot be achieved unless the procedures and policies are well codified. It will be very hard for a senior manager to be fair, or be seen to be fair, if each decision seems to be an ad hoc one. Thus the rules have to be clear. However the proper codification of policies does not automatically result in an overly rigid bureaucracy; on the contrary, flexibility in making exceptions to the rules can be most effectively executed when the rules are well established and well-known. The establishment of clear rules and the spelling out of well-defined procedures in an efficient, streamlined administration do not mean a proliferation of paperwork. A requirement of many copies and many approvals is not synonymous with good controls. It may be just the opposite.

Participatory Management

In the entire range of activities involved in the management of a research institution, from the establishment of the administrative procedures to the elucidation of overall research policies and priorities, the individual scientists must be brought into the decision-making process.
The ability to permit participation by subordinates and others without the feeling of being threatened is a recognized characteristic of successful executives. This quality is particularly essential in scientific research management. Arnon pointed out, too, that people who staff research institutions are those who "by training and inclination have usually been conditioned to averseness to administration in all of its manifestations". Later he stated "the whole concept of superior-subordinate relationship, as it exists in governmental or industrial organizations, is uncharacteristic of the relationships between the different levels of research leadership. The need for decentralization, delegation, participation and consultative management, as stressed by the human relations approach, is applicable to research organizations".

The advantages of shared deliberations include the development of a close relationship between the research director and the senior research workers; the development of a feeling of common purpose, shared interest, and a sense of involvement; stimulation of awareness of problems with which the organization is faced; improvement of communication, with opportunities for emphasis and clarification where required; and the fact that collective judgement may be more effective than individual judgement and that a check-and-balance system helps to prevent arbitrary decision-making by individuals. Some disadvantages of sharing deliberation include the use of valuable researchers' time and the fact that researchers often do not have a sufficiently broad understanding of the problems involved. Because they are more concerned with their individual subject fields than with institutional requirements or policies, they tend to resist proposals that might encroach on existing prerogatives.

In spite of their obvious and well-known weaknesses, shortcomings and even dangers, committees seem to present the best mechanism for introduction of participatory management into a research institution. While this does use valuable scientist time, the resulting improvement in communications and the feeling of involvement that results from the interaction in these committees more than offset the time lost. Indeed there is evidence that scientists are most effective when involved part-time in other activities such as teaching and administration. In a survey of 522 scientists in engineering in 11 industrial, governmental and university research units, it was found that scientific performance (as measured by scientific or technical contribution and by general usefulness to the organization)

---

for Ph.D.'s and assistant scientists was highest for those who spent three-quarters of their time on scientific work.\textsuperscript{11}, \textsuperscript{12}

The use of committees provides great benefits in improved communication, understanding and a sense of participation derived from involving scientists in the process of major policy decisions. This process also contributes greatly to the quality of the decisions made and the morale and productivity of the institution. The director bears the ultimate responsibility for the institute's policies; only he\textsuperscript{*} can balance group judgement on one hand with the needs and goals of the organization on the other. Thus, while the various committees must have different degrees of executive authority, normally they are advisory in nature. Whereas the director must maintain the right to make the final decision, he is well advised to act contrary to the considered judgement of committees he has appointed only rarely and after careful consideration.

Delegation of Responsibility and Authority

In the same way as a research manager is able to do a better job of decision-making by involving others in participatory management, he is able to be a more efficient and effective executive to the extent that he appropriately delegates responsibility and authority. As mentioned above, the final responsibility for management of the institute must rest on the director. However, only by delegating a major portion of his authority will he find time and freedom to handle adequately the many functions which evolve uniquely on him. Making the important strategic decisions and developing a sound research philosophy for the institution require

\textsuperscript{*} The words "he", "his" and "him" are used in a generic sense when referring to research directors or scientists who may, of course, be male or female.
unhurried deliberation and wise advice. This requires time for thought as well as adequate communication. Only the director can perform some of the representation duties required for government relations and donor support. None of these functions can be performed well by a harassed chief, overly burdened by details which can and must be handled by subordinates.

Everyone knows that responsibility must be delegated; the mistake many managers make is to delegate responsibility without passing on commensurate authority. The most basic principles of classical organization theory first put forward by Fayol\textsuperscript{13} and supported by many schools of management science since, emphasize that authority and responsibility should be commensurate; that is if a person is made responsible for a certain function and task he must be given authority to ensure that he is able to carry out his obligations. Delegation of authority is ineffective if it is not visible and consistent. For example, when an area of responsibility has been handed over to a subordinate, it is that person who should sign the memos and the approvals related to that area of activity. Too often it is easier for the chief executive to take action himself in an area he has already given to someone else. This temptation must be resisted or schizophrenic administration will result.

Delegation of authority and responsibility includes allowing subordinates to make mistakes and supporting them even when not fully in agreement with their decisions.

While I have repeatedly referred to the "director" as though he were a single person, much of what has been stated above applies equally to the several people who make up the top management of a research institution. Furthermore, in the same way as interdisciplinary teams are often the best way to organize problem-solving research, I have found "team management" to be an effective means of directing a research institution. Such team management is characterized by a broad sharing of responsibilities between the head of the institution and his close subordinates, along with a system of open communication, which keeps all members of the team informed about the actions of the others and makes it possible for any one to take on the responsibilities of another when necessary.

RESEARCH MANAGEMENT

Having dealt with some of the principles of the management of a research institution, I now wish to comment on some aspects of the management of the research conducted in that institution.

Functions of Research Management

Breck\textsuperscript{14} described management as the determination of objectives, the laying down of a broad policy for the achievement of these objectives and the translation of that policy into programs for action. He summarized these functions as planning, organizing, leading, motivating, and controlling. Kidd\textsuperscript{15} defined administration of research as "research planning on a broad scale, the development of scientific strategy, the evolution of a consistent philosophy of research, and the difficult tasks of bringing a sound philosophy to bear upon the conduct of research".

For the purpose of this paper I have organized discussion into three topics: planning and evaluating research, organizing research and personnel management.

Planning and Evaluating Research

You may have noted that in my presentation so far I have used the terms "research manager" and "research director" somewhat interchangeably when referring to the person or persons in charge of a research institution. This is not surprising. If one accepts that agricultural research is the application of scientific principles and knowledge to the solution of agricultural production constraints, then, by definition, agricultural research activities cannot be interest-oriented, or opportunity-oriented, but must fit within a directed program oriented

toward the solution of specific problems, a condition incompatible with the free choice of research subjects. Thus the scientists in an agricultural research institution must work within the framework of a plan, and research management involves a strong sense of direction.

Koontz and O'Donnell defined planning as "the executive function which involves the selection, from among alternatives, of enterprise objectives, policies, procedures and programmes". There is more literature on the subject of agricultural research planning than on many other aspects of research management. I will, therefore, not go into detail on this subject in this paper. However, I do wish to point out the importance of setting priorities and making the hard decisions of what to emphasize and what to leave undone. One of the most general, firm impressions I have perceived in visiting many national research programs is that too much is being attempted with the resources available. In order to be effective, national, regional and international institutions must carefully analyze priorities and decide to concentrate efforts on a limited number of the most important commodities and research subjects. Similarly, every ecological zone cannot be adequately covered and many national research programs have too many stations for each to be properly staffed, equipped and financed. The reduction of these to those which can be operated efficiently with a critical mass of scientists will also require some very hard decisions. In this respect, planning cannot be separated from evaluation. Usually resources are limited; therefore the introduction of a new activity or expansion of an existing one often means a shift in resources already engaged elsewhere. Scientific programs must be regularly evaluated to determine whether or not any should be discontinued. As Irving colorfully puts it, "those most closely involved are most likely to see a need for continued research, just one more step and then another. In some cases the end comes not by natural death but requires administrative euthanasia." Setting priorities involves not only the research director; he must depend on the informed advice of his colleagues. While much of the information on the establishment of priorities is intuitive, careful

ex-ante economic analysis to determine the costs, as well the amounts and
distribution of the socio-economic benefits anticipated from the research,
provides a valuable tool in the planning process.

One further point I wish to make regarding the evaluation of research
programs and projects is the importance of a peer review. Clearly, the
scientists must be involved in the evaluation process. Recognition,
approval and evaluation of his work by his peers is an important motivational
force for a scientist, and peer review provides informed opinion which would
not otherwise be available to the research management. The procedure of an
annual, in-house review (IHR) has become generally enshrined within the
International Agricultural Research Centers. Dr. Jock Anderson, an
Australian scientist who was a Visiting Scientist at CIMMYT, published an
excellent review of the IHR procedure. He stated that in spite of the fact
that this takes an entire week of scientists' busy time, they "seemingly
approach the IHR with enthusiasm and vigor". He pointed out that one of the
important features in such a review is its comprehensive nature, and
indicated that the feeling of "all in it together" is important in discouraging
feelings of victimization and transparent vulnerability that must always
accompany any probing criticism of research work in progress. He noted the
open, constructive atmosphere for in-depth criticism in this process, which
requires particular personalities who can direct and lead discussions along
perceptive and useful channels and who can criticize work without insult
or personal attack. Anderson considered the process sufficiently effective
that he recommended it for use within Australian agricultural research
organizations. I believe it can be applied usefully to many national
research institutions as a key component in the evaluation process.

Personnel Management

I have purposely passed over the important functions of planning and
evaluation rather superficially in order to leave adequate time for what I
consider to be the most important single component of research management.

18/ Anderson, J.: Forum on Formalized Opinion of Peers in Monitoring
The essence of research management is the art of managing scientists. Much attention is given to resource allocation, program planning and evaluation and different institutional models, but in the end it is the scientist who is the key component to successful agricultural research. Without well qualified, well motivated, well-led scientists, the most adequately funded, best-equipped and best-organized research institution is useless. Thus, the most important role of the research manager is the "care and feeding" of research scientists. While the research director cannot devote all the time he would like to many aspects of his work, personnel decisions should never be made hastily. Whether it is in recruiting, reviewing the activities of individual scientists, or dealing with personal problems, no effort or time should be spared to do this part of the research management job well.

Selection

Research institutions spend 70% or more of their budget on personnel; yet the matter of recruitment and selection is often done routinely and without sufficient in-depth analyses. I had the pleasure of serving as a Visiting Scientist in the International Rice Research Institute in 1964 during its formative years. Naturally, when I first arrived I was favorably impressed by the quality of the facilities. However, the more important and lasting impression was the uniquely high quality and high motivation of the scientists I found there. The late Dr. Sterling Wortman was at that time Associate Director for Research, under the strong leadership of an outstanding administrator, Dr. Robert Chandler. In this capacity Dr. Wortman was responsible for a major part of the scientific staff recruitment. Years later, when I was a research director myself, I asked him what was the secret of his success in recruiting such outstanding scientists. He did not hesitate a moment in his reply: the most important ingredient to the recruitment of scientists, he said, is to have a very clear understanding of what that person was going to do and how he would fit into the overall institute program before beginning the recruitment process. This is an important distinction, because so often research institutions do it the other way around, attempting to fit the scientist to the job or fit the job to the scientist rather than to select the most outstanding scientist, uniquely qualified for the specific task at hand. Let me give a simple illustration. If a particular research program needs a field-oriented crop physiologist and the candidate selected is a laboratory-oriented biochemical physiologist, it will be very difficult to change his nature and interests, regardless
of how intelligent and motivated he may be. On the other hand, changing the job to fit the scientist recruited changes the whole nature of the program. Thus I have learned to recognize the wisdom of Dr. Wortman's advice.

Since I have emphasized the value of interdisciplinary team research, two points that relate specifically to recruitment for such organization should be noted. One is that the ability of the candidate to work as a harmonious member of a team should be considered along with other qualifications. The other is the importance of a degree of involvement of team members in the selection of potential future colleagues.

**Motivation**

Of course scientists must be adequately remunerated and those performing exceptionally well must receive special merit increases to reward good performance. Many national programs are unable to provide adequate compensation or differential merit awards because they are tied to a civil service system. Fortunately there is a strong trend to establish agricultural research institutions as autonomous or semi-autonomous organizations, which is beginning to help overcome this important problem. However financial remuneration is not enough. Even more important, in my opinion, is that the scientists must feel that what they are doing is important and know that their work is recognized and appreciated. In the field of agricultural research, particularly in developing countries, we have the distinct advantage of having little trouble in finding grounds to convince scientists that their work is indeed very important. What could after all be more important than contributing to the solution of hunger and poverty today? Recently a research manager was telling me that the role and importance of agricultural research was not adequately recognized by government officials and policy-makers. This was not surprising; but what shocked me was when he went on to say that even the individual scientists did not seem to recognize that what they were doing was important, but merely doing their own thing without an understanding of how their work contributed to the whole. While as a guest I couldn't say so, I was tempted to say, "well, what are you doing about it?", since the motivation of scientists to
understand the important role of the institute and the key role they play in it is one of the most important duties of a research manager.

I have found that good working conditions are also probably more important than monetary remuneration for the motivation of scientists. This means not only adequate research facilities but also appropriate administrative policies that minimize bureaucratic constraints and maximize the amount of support the scientist receives.

Finally in the area of motivation, I cannot over-emphasize the importance of recognizing each scientist as an important, individual human being, with problems, concerns, ambitions and pride which must be recognized with concern, interest and compassion. In a study carried out by the University of Michigan, which investigated the relationship between supervision and research performance, it was found that frequent stimulation and encouragement from the supervisor contributed to high research performance.8/ In my experience, it is often the most productive scientists who require the most attention. The research manager who dismisses such personnel as prima donnas or troublemakers is foregoing a very valuable asset.

Some scientists will seek attention; others are more shy. In order to insure that all have opportunity to express their views and report personally on their activities, a systematic program for meetings of the research director with the individual scientists should be established.

Leading

While I have stated that the research in an agricultural research institution must be directed and have mentioned "control" as one of the important functions of research management, such direction and control can be applied effectively only through leading and guiding in an atmosphere of persuasion and consent. Scientists, probably even more than others, are usually allergic to excessive control, even if exercised by other scientists. A good research leader provides scientific guidance without stifling initiative. He cannot do so without occasionally having to criticize. However, the right to criticize is earned by praising when praise is due. An effective leader will, therefore, actively seek opportunities for genuine praise (not flattery), and when criticism is necessary will be careful to criticize the performance rather than the
person. Blanchard and Johnson\(^{19}\) pointed out the importance of reprimanding the behavior only and never attacking the person's worth or value as a person. They also emphasized the need for each person to have very clearly stated goals and objectives. This is in contrast to what they refer to as the "leave alone-zap" style which characterizes some leaders who never make it quite clear to a person how he is doing but save all the criticism for the annual evaluation. It is much better to set clear objectives so that staff know what is expected of them and let them know when they are doing things right and when they are doing things wrong.

If the research manager has been careful in the selection of the scientists and has clearly outlined their areas of responsibility, then he can give the scientists ample range for personal initiative. I like to remind our scientists that what we expect from them is relevance and responsibility and in return we in the administration owe them trust and flexibility.

The foregoing emphasis on participatory management, on concern and attention to the individual, and on trust and flexibility should not be interpreted as giving license to sloppy, unstructured management. Discipline is also important. Those who do not respond to a concerned and flexible administration with responsibility must be dealt with accordingly. The good research manager is compassionate in relation to personal problems but must be firm when it comes to matters of performance and discipline.

**Taking and Making Time**

One of the most precious commodities of a research manager is TIME. There are simply not enough days in the week, hours in the day, or minutes in the hour to accomplish everything it seems he should do. And yet I have stressed the importance of making decisions and handling personnel matters in a relaxed, unhurried atmosphere. When a scientist comes to see his director about a problem, which to him is the most important in the world,

The effective research manager, therefore, must develop a strategy to make time available. Such a strategy should not be based on merely working longer. I am not impressed by the research manager who consistently works excessively long hours. Naturally, there are emergencies when certain deadlines must be met, and when evenings or weekends must be devoted to the task. However, this should be the exception rather than the rule. The type of intense concentration which is required for effective research management simply cannot be sustained by most human beings much longer than the normal working day. While most research managers will not be able to adhere strictly to an 8 to 5 day, and clock-watchers are to be avoided, one who works excessively long hours consistently is probably not very productive in those extra hours.

More important than working longer is better using the time available. How can this be done? One way is to delegate responsibility, which has already been discussed above. The other is to improve the organization in the use of time.

In order to have the time to give careful consideration to policy and personnel questions it is essential to set aside sustained periods which will be uninterrupted. I do not believe that a research director can afford to have totally "open door" policy. He must have a "closed door" and an effective secretary who will keep him from being uninterrupted (except for emergencies) for a certain period of time each day, while reserving another period for fixed appointments and on ad hoc visits. It is amazing how much more can be accomplished in an uninterrupted hour than in 12 five-minute periods. No doubt there are other ways of improving time management, but the key word is organization, and the research director will never be able to efficiently manage his time unless he finds some way to deal expeditiously with the large volume of paper which crosses every executive's desk. In this regard, I have found the advice the late George Harrar gave me when I first became an administrator, to try and handle any piece of paper only once, very helpful.

**Characteristics of a Good Research Manager**

The foregoing discussion can probably best be summarized by describing some of the qualities which will characterize a good research leader.

1) **He is fair, honest and consistent**
2) **He cares about individuals**, is concerned for their welfare, and demonstrates interest in their individual activities. Small things such as going to the office or laboratory to see a scientist rather than having him come to the administration office, and being careful to attend seminars, symposiums and conferences given by the scientists, demonstrate such interest and respect.

3) **He is respected.** Everyone wishes to be liked, but this is not always possible and the research manager who tries too hard to be a "nice guy" will not be able to make the inevitable tough decisions. Even unpopular decisions, when made with integrity, will earn the respect of staff, which is more important than their love.

4) **He is decisive.** I have heard that a chicken crossing the road is an example of a poor executive, in that the chicken waits until the last moment to make the decision and then makes the wrong one. Many times even a wrong decision is better than no decision at all. Research managers have to be willing to make mistakes, although it is hoped they won't make too many.

5) **He delegates responsibility and authority and supports the actions taken by his subordinates.**

6) **He is a full-time research administrator** who enjoys the art of management and has decided to make it a career. Too many scientists, experts in their particular field, attempt tenaciously to continue their own research activities after having taken on important administrative responsibilities. The insidious danger of trying to keep a foot in both camps, attempting to keep full involvement in the direct conduct of research but reluctant to give up the prestige of an administrative post, must be avoided. The result is usually a poor scientist and a poor administrator. Research institutions should choose as their leaders those who have decided to make scientific administration a career.
7) He is a good communicator. The need for good communication with scientists and other staff members has already been discussed above. In addition, a research manager will need to be skilled in speaking and handling the written word with clarity and felicity.

8) He insists on excellence. The job of increasing agricultural production is simply too important to be done in mediocre fashion. Excellence is not usually more expensive; it just requires better motivation and organization. One of the other things which impressed me as a Visiting Scientist at IRRI was the emphasis on excellence that resulted in the quality of the work produced. Chandler, describing the history of IRRI since 1968, related how he continuously reminded staff that those who judged IRRI would base their opinions on whatever contact they happened to have with it. If they received a letter with grammatical or typographical errors or if they observed that the grounds were not neatly maintained, or that the drivers were careless and over-relaxed, they might assume that the Institute's research program was slackly run as well. He stated that he "stressed the importance of doing a quality job in every department and operation and urged all to take pride in helping IRRI establish a first-class reputation." I believe all our institutions will benefit by such an emphasis on high standards.

CONCLUSION

In conclusion, I wish to turn from the specifics of managing a research institution to the broader subject of agricultural research in the Caribbean. This workshop presents a rare opportunity to strengthen agricultural research in this region; gathered together here are research leaders, government policy-makers, representatives of international organizations and donors—all of which have a vital role to play. This timely opportunity presents us all with a challenge to act with

boldness and dedication in a spirit of cooperation. We must act with
boldness to challenge existing organizational structures and management
procedures to find those who will make it possible to establish clear
priorities and pursue these objectives efficiently. We must find ways
to work together more effectively. Our task is too important-- and the
resources available too limited-- for us to tolerate wasteful duplication.
And we must dedicate ourselves totally to the noble task of improving
human welfare through increased agricultural production. Too many
peoples' lives and well-being depend on our efforts for us to do less.
