Abstract

Network analysis techniques offer a powerful means for studying the connections between countries within international production networks. This document adopts a network analysis approach to examine the vertical trade relations between Latin America and Asia, showing the potential of these techniques for providing new insights into the patterns and dynamics of countries' GVC linkages. Particularly, network-based measures are used to assess how important countries are as users and suppliers of foreign intermediate inputs in each network, at both the aggregate and sector level. In addition, clustering techniques are applied to identify groups of supplier countries.

The analysis shows the expansion experienced by Latin America-Asia vertical integration between 2000 and 2014. Particularly, it highlights the increasingly central role played by China, both as a user of inputs imported from Latin American countries and as a supplier of intermediates for these countries' exports. The document also shows the asymmetric nature of the linkages between the two regions, where Latin America is largely specialised in supplying primary and relatively low-technology manufactured inputs while importing more technology-intensive intermediates.

Introduction

Latin America's trade with Asia increased rapidly since the early 2000s, as China emerged as a major player in the world economy. The share of Asian countries in Latin American goods exports rose from around 15% in 2000 to nearly 30% in 2014, while their participation in the region's goods imports increased in this period from less than 7% to around 20%. Yet, the asymmetric nature of these trade linkages, in which Latin America exports a small range of primary products and low-technology manufactures and imports a larger variety of higher-technology goods, poses challenges for the region in terms of diversification and upgrading (i.e., shifting toward higher value-added products and tasks).

The pattern of Latin America-Asia trade relations reflects these regions' roles in global value chains (GVCs). While many Asian economies have successfully integrated into different stages of international production networks, by specialising in niches of the manufacturing process, Latin American countries' GVC participation has been predominantly limited to supplying relatively unprocessed natural resource-based inputs to other countries downstream (Blyde, 2014; Cadestin et al., 2016).

This document adopts a network analysis approach to provide new insights into the extent and nature of vertical trade links between Latin America and Asia (i.e., their trade in intermediate inputs that are used to produce each region's exports). Network analysis offers a powerful means for representing patterns of connections between countries within international production networks. Since the first applications of these techniques to the characterisation of world trade (e.g., Serrano and Boguñá, 2003; Garlaschelli and Loffredo, 2005; Kali and Reyes, 2007), a growing body of literature has explored the use of network analysis to the study of GVCs. Using bilateral trade data, Ferrarini (2013) introduces the visualisation of trade associated with international production chains in the form of network maps, and quantifies the intensity of vertical trade among the countries and industries participating in global production sharing. Also on the basis

of bilateral trade data, Cingolani et al. (2017) propose a three-faceted measure of centrality that captures countries' distinct roles at the upstream, midstream, and downstream stages of the international production process. Studies based on inter-country input-output (ICIO) data include Zhu et al. (2015), who investigate the topological properties of industry-level GVCs, represented as global value trees that capture the value-added flows between industries in different countries. De Benedictis and Tajoli (2016) evaluate the evolution of Italy's comparative advantages, both in gross terms and in value added, through the visual and topological representation of its position in the network of world trade. Amador and Cabral (2017) provide a general picture of the nature and dynamics of GVCs from a binary-network perspective, examining analytically and graphically the international flows of value added. Amador et al. (2018) use weighted network metrics to investigate the specific roles of different countries within GVCs and quantify their relative importance over time. Also, Zhu et al. (2018) compare GVCs across countries, introducing a network-based measure of similarity that takes into account both direct and indirect relationships between country-sector pairs.

Here, information from input-output tables is combined with bilateral trade data to describe the patterns and dynamics of vertical trade between Latin America and Asia along the period 2000-2014. Particularly, network-based measures are used to assess how important countries are as users and suppliers of foreign intermediate inputs in each network, on the basis of their weighted in-going and out-going connections. In addition, clustering techniques are used to identify groups of supplier countries.

The document is organised in three sections. Section I describes the methodology and data underlying the analysis. Section II presents the characterisation of Latin America and Asia's vertical trade relationships. Finally, section III concludes.

I. A network analysis of gross vertical trade

Vertical trade refers to the use of foreign intermediate inputs to produce countries' exports. In gross terms, countries' forward linkages in international value chains are reflected in their exports of intermediate inputs that are incorporated into other countries' exports, while backward linkages are given by the foreign intermediates used in the production of countries' own exports. This document adopts a network analysis approach to study the patterns and dynamics of gross vertical trade between Latin America and Asia along the period 2000-2014, combining input-output information from the Organisation for Economic Cooperation and Development (OECD) with bilateral trade data from the *Centre d'Études Prospectives et d'Informations Internationales* (CEPII)'s *Base pour l'Analyse du Commerce International* (BACI).¹

Network analysis provides useful tools to visualise and synthetically represent international trade flows. Particularly, it allows for studying trade linkages in a structural way, taking into account the interdependence amongst all participant countries (De Benedictis et al., 2013; Amador et al., 2018). Thus, trade relations between each country-pair are not analysed in isolation but considering the full set of relations in the network (i.e., each country's relation with every other participating country). This is particularly useful for assessing the nature and dynamics of countries' GVC linkages.

International value chains are represented here as weighted directed networks where countries (nodes or vertices) are linked by bilateral vertical trade flows (edges).² The analysis focuses on Latin American and Asian countries' gross backward linkages, measured by the

¹ For details on the construction of the dataset, see annex 1.

² In directed networks each edge has a direction, pointing from one node to another (here, from the input-exporting country to the input-importing country). In contrast, undirected networks ignore the direction of the edges (if there is any).

imported intermediate goods used to produce these countries' manufacturing exports (excluding energy inputs). The input-output data available allow to include 7 countries from Latin America (Argentina, Brazil, Chile, Colombia, Costa Rica, Mexico, and Peru) and 14 Asian countries (Brunei Darussalam, Cambodia, China, Hong Kong, India, Indonesia, Japan, the Republic of Korea, Malaysia, Philippines, Singapore, Taiwan, Thailand, and Viet Nam) as importers of foreign inputs (i.e., recipients of the directed edges). The countries supplying these inputs (i.e., origin of the edges) are 220, including 33 from Latin America and the Caribbean and 17 from Asia.³

It should be noted that the reduced availability of inter-country input-output data for Latin American countries imposes two limitations to the analysis performed in this document. First, the use of gross vertical trade data implies that both the domestic and foreign value embodied in traded inputs are considered, not just the value added in the exporting country. Measures based on trade in value added would allow quantifying countries' actual contribution to the value generated in each stage of the production chain, capturing direct and indirect inter-country linkages. Second, most Latin American economies are considered here as supplying countries but not in their role as input-importing countries, which prevents from taking into account the complete set of interconnections amongst Latin American and Asian economies, as well as that of intra-regional linkages within Latin America.

This section presents the indicators used to assess countries' roles as users and suppliers of foreign intermediates in each of the two networks considered —referred hereafter as Latin America (7 countries) and Asia (14 countries)—, on the basis of their in-going and out-going connections. It also describes the cluster analysis performed to identify groups of supplier countries in each network.

A. Centrality measures

Centrality measures allow quantifying how important (central) nodes are in a network. They can be used to evaluate how relevant a country's participation in international value chains is. The simplest measure of centrality is node degree, often referred to as degree centrality, given by the number of edges connected to the node. In directed networks nodes have two different degrees, in-degree and out-degree, corresponding to the number of in-going and out-going edges, respectively.

Here, links between countries are weighted by the value of the vertical trade-related intermediate goods exchanged. Thus, extending the definition of node degree to the case of a weighted network (Barrat et al., 2004), countries' in-strength (s^{in}) —computed for the 21 Latin American and Asian importers included in the analysis— is given by the total value of the foreign intermediate goods embodied in each country's own exports. Countries' out-strength (s^{out}) —computed for the 220 supplier countries considered— is the total value of the intermediate

³ The analysis in this document focuses on the value chains linking Latin America and the Caribbean with East and South-East Asia. Unless otherwise indicated, this last region (for simplicity, referred to as Asia) comprises the following countries: Brunei Darussalam, Cambodia, China, Hong Kong (Special Administrative Region of China), India, Indonesia, Japan, the Republic of Korea, Lao, Macao, Malaysia, Myanmar, Philippines, Singapore, Taiwan (Province of China), Thailand, and Viet Nam. Other Asian countries are included in the aggregate rest of the world. The list of all the countries considered in the analysis, and their three-letter ISO codes (used in tables and figures), is given in table A.2 in annex 2.

goods supplied to other countries' exports. Both measures are normalised by the total weight of the network (being therefore expressed in percentage terms):

$$S_p^{\text{in}} = \frac{\sum_q w_{qp}}{\sum_q \sum_p w_{pq}} \quad (1)$$

$$S_p^{\text{out}} = \frac{\sum_q w_{pq}}{\sum_q \sum_p w_{pq}} \quad (2)$$

where w_{pq} , the pq th element of the weighted adjacency matrix, is the value of the intermediate goods from source (exporting) country p embodied in (importing) country q 's exports (with $w_{pq} = 0$ for $p = q$).⁴

Countries' centrality can also be assessed by identifying the so-called hubs and authorities in each network. The hub and authority centralities of a country are related to the centralities of the countries it is connected to. A hub is defined here as a country that supplies a large amount of intermediate goods to countries that are important users of foreign inputs in their exports (i.e., countries that have a high in-strength centrality). An authority is a country whose exports embody a large amount of intermediate goods from countries that are important suppliers (i.e., countries that have a high out-strength centrality). A hub may also be an authority, and vice versa. Thus, the hub and authority centralities quantify countries' relevance in the two roles: the hub centrality reflects countries' prominence as suppliers of foreign intermediates to other countries' exports, whereas the authority centrality indicates countries' importance as users of foreign intermediates in their own exports (analogously to the out-strength centrality and the in-strength centrality, respectively).

The centrality algorithm called hyperlink-induced topic search (HITS), developed by Kleinberg (1999), works iteratively computing hub and authority scores for each node. These scores, defined in terms of one another and initialised to 1, are updated during each iteration as follows:

- the authority centrality of node p (aut_p) is proportional to the sum of the (previous iteration's) hub centralities of the nodes that point to node p

$$aut_p(n) = b(n) \sum_q w_{qp} hub_q(n-1) \quad (3)$$

- the hub centrality of node p (hub_p) is proportional to the sum of the (current iteration's) authority centralities of the nodes it points to

$$hub_p(n) = c(n) \sum_q w_{pq} aut_q(n) \quad (4)$$

where n is the iteration number; and b and c are normalisation factors that make the squares of the authority and hub scores, respectively, sum to 1 (i.e., $\sum_p [aut_p(n)]^2 = 1$, and $\sum_p [hub_p(n)]^2 = 1$). The algorithm is considered to have converged when the scores become stable (i.e., the change between one iteration and the next is below an arbitrarily small value, set here at $1E-10$).

From equation (3), authority centrality will be larger for countries with significant imports from countries with large hub centrality. Similarly, from equation (4), hub centrality will be larger

⁴ The adjacency matrix is used to represent networks, capturing their structure. In its binary form, the elements of the adjacency matrix (a_{pq}) take the value 1 if there is a link (edge) between the corresponding nodes (in directed networks, a link from node p to node q), and 0 otherwise. The elements of the weighted adjacency matrix (w_{pq}) are the weights (strength) of the links between the corresponding nodes.

for those countries with significant exports to countries with large authority centrality. Thus, both metrics are interrelated, strengthening and reinforcing each other (Deguchi et al., 2014).

B. Community detection

Another relevant area of network analysis is that of community detection or clustering, consisting in the division of nodes into groups, clusters or communities on the basis of topological features extracted from the network (e.g., the density of links between nodes), or additional information on characteristics related to the nodes and edges.

Here, the K-medoids clustering method (particularly, the partitioning around medoids (PAM) algorithm) is used to identify groups of supplier countries in each network. A cluster is defined as a set of countries that are closer each other, compared to the rest of supplier countries in the network, according to a measure of distance or dissimilarity. This dissimilarity measure is computed on the basis of the composition of countries' vertical trade-related intermediate exports, in terms of the share of agricultural, mining, low-technology, medium-low-technology, and medium-high or high-technology inputs.^{5,6}

The PAM algorithm is based on the search for k nodes, called medoids, that should represent the structure of the data (Kaufman and Rousseeuw, 1987). These representative nodes are the most centrally located nodes in each cluster.⁷ After selecting an initial set of medoids, clusters are formed by assigning each non-selected node to its most similar medoid (build phase). Subsequently, medoid and non-medoid nodes are exchanged (swap phase), until the sum of dissimilarities between the nodes and their closest medoid (the objective function) can no longer be decreased. At each iteration, an original medoid is replaced with the node that causes the greatest reduction in the objective function (if there is any). The set of best nodes for each cluster form the new respective medoids, and non-medoid nodes are re-assigned. As a result of this procedure, the nodes assigned to each cluster should have a high degree of similarity, while nodes belonging to different clusters should be as dissimilar as possible.

As it is frequently the case in cluster analysis, the number of clusters present in each network is not known *a priori* here. The PAM algorithm is therefore computed using different values of k , and the optimal cluster structure is determined by means of the so-called silhouette coefficient (Rousseeuw, 1987). This coefficient evaluates clustering quality by combining information about inter-cluster separation and intra-cluster compactness:

$$SC_p(k) = \frac{\bar{d}_p^B(k) - \bar{d}_p^W(k)}{\max\{\bar{d}_p^W(k); \bar{d}_p^B(k)\}} \quad (5)$$

⁵ Dissimilarity between countries is measured by the Euclidean distance, given by: $d_{pq} = \sqrt{\sum_i |x_p(i) - x_q(i)|^2}$, where $x_p(i)$ and $x_q(i)$ is the share of the i -th category of inputs in countries p and q 's exports, respectively.

⁶ The technology-intensity classification of manufacturing industries considered in this document is based on that of the OECD. For details, see table A.1 in annex 2 and ISIC Rev. 3 Technology Intensity Definition (OECD, online document: www.oecd.org/dataoecd/43/41/48350231.pdf).

⁷ K-medoids clustering is a robust alternative to K-means clustering, less sensitive to outliers. While in K-means clustering the centre of a given cluster is calculated as the mean of the member nodes, which is greatly influenced by extreme values, K-medoids uses the most centrally located node (i.e., that for which dissimilarity with all the other members of the cluster is minimal).

where \bar{d}_p^W is the average dissimilarity of country p to all other countries in its own cluster (within dissimilarity); \bar{d}_p^B is the average dissimilarity of country p to the members of its neighbouring cluster (i.e., the smallest between dissimilarity); and k is the number of clusters considered.⁸

For each country p , SC_p ranges between -1 and 1. A value close to 1 implies that within dissimilarity is much smaller than the smallest between dissimilarity, so country p is well-clustered. In contrast, a value close to -1 would imply that country p is misclassified, as within dissimilarity is much larger than the smallest between dissimilarity. A small value of SC_p (around 0) means that the country lies between two clusters.

The optimal number of clusters in each network (k^*) is given by that that yields the largest overall average silhouette width (i.e., the average of SC_p for the P supplier countries in the network), computed as:

$$\overline{SC}(k) = \frac{\sum_{p=1}^P SC_p(k)}{P} \quad (6)$$

⁸ To avoid confusion with subsection A, the notation in equation (5) differs from that used in Rousseeuw (1987).

II. Latin America and Asia's vertical trade integration

A. Vertical trade networks: relevant players, hubs and authorities

Vertical trade integration between Latin America and Asia is first approached here by assessing countries' roles as users and suppliers of foreign intermediates in each network (i.e., Latin America (7 countries) and Asia (14 countries)), based on the centrality measures described in section I.

The analysis of countries' in-strength centrality shows that Mexico —highly integrated into North American value chains— concentrates the bulk of the in-going vertical trade-related intermediate flows in Latin America (7 countries), while China is largely the main user of imported inputs within Asia (14 countries) (see figure 1). China also plays a central role in both networks as a supplier of foreign intermediates to other countries' exports, as revealed by its out-strength centrality (see figure 2). Although the United States remains as the main input supplier for Latin America (7 countries) —mostly Mexico—, it has lost much ground to China. In Asia (14 countries), China's out-strength centrality has also increased significantly since the early 2000s, to the detriment of Japan and the United States.

The increasing relevance of China, in the role of both user and supplier of foreign intermediates, reflects this country's rise as a major global manufacturing centre in the 2000s, after its accession to the World Trade Organization (WTO). This is also evident when considering the global network made up of the 63 countries covered in the OECD's ICIO tables (see figure 3).

Latin American and Caribbean countries do not play a relevant role as suppliers of foreign intermediates (see figures 2 and 3). Particularly, these countries' weak intraregional linkages contrast with those of Asian economies, although there are significant differences between Mexico and the other countries encompassed in Latin America (7 countries) (referred hereafter as Latin America

(6 countries)). While Latin America and the Caribbean accounts for only 3% of the foreign inputs embodied in Mexican manufacturing exports, it represents over 30% of the total in Argentina and Chile (see figure A.1 in annex 2). For Asia (14 countries), the share of intraregional inputs ranges between 38% (India) and 95% (Cambodia), with an average of 66% (see figure A.2 in annex 2). Yet, the level of intraregional linkages —as well as countries' overall out-strength centrality— varies greatly across inputs' origin sectors.

Figure 1
Latin America (7 countries) and Asia (14 countries): in-strength centrality in regional networks, 2000 and 2014^a
(Percentages)

Source: Author's calculations on the basis of input-output data from the Organisation for Economic Cooperation and Development (OECD)'s ICIO tables.

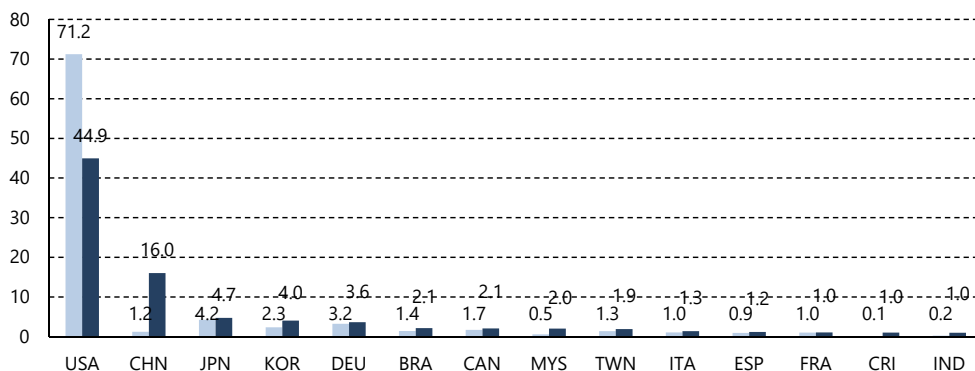

^a Countries are shown in descending order according to their in-strength centrality in 2014, which is normalised by the total value of the foreign intermediate inputs embodied in the corresponding network's manufacturing exports (i.e., Latin America (7 countries) and Asia (14 countries) for figures 1.A and 1.B, respectively).

Latin American countries, particularly those from the South American subregion and mostly at the intraregional level, show relatively large out-strength centralities in agriculture, mining and natural resource-based manufacturing sectors (including Food products, beverages and tobacco, Pulp, paper and paper products, and Basic metals). Except for Basic metals, these sectors account for a rather small share of the foreign intermediates embodied in Latin American and Asian countries's manufacturing exports (see tables A.3 to A.5 in annex 2). Brazil and, to a lesser extent, Argentina and Mexico also play a significant role as intraregional suppliers of more technology-intensive inputs (Motor vehicles,

Electrical machinery and apparatus, n.e.c., Computer, electronic and optical equipment, depending on the country). In addition, Costa Rica and Mexico have a rather significant participation as a source of some high-technology inputs for Asian manufacturing exports (Computer, electronic and optical equipment and Motor vehicles, respectively).⁹

Figure 2

B. Asia (14 countries)

Source: Author’s calculations on the basis of input-output data from the Organisation for Economic Cooperation and Development (OECD)’s ICIO tables; and trade data from the Centre d’Études Prospectives et d’Informations Internationales (CEPII), Base pour l’Analyse du Commerce International (BACI).

^a Countries are shown in descending order according to their out-strength centrality in 2014, which is normalised by the total value of the foreign intermediate inputs embodied in the corresponding network’s manufacturing exports (i.e., Latin America (7 countries) and Asia (14 countries) for figures 2.A and 2.B, respectively). Countries with a strength centrality of less than 1% in 2014 are not shown.

⁹ The closure of Intel’s microprocessor assembly plant in 2014 has caused a sharp decline in Costa Rican exports of electronic components.

Figure 3
Selected countries: in and out-strength centrality in the global (63 countries) network, 2000 and 2014^a
(Percentages)

Source: Author’s calculations on the basis of input-output data from the Organisation for Economic Cooperation and Development (OECD)’s ICIO tables; and trade data from the Centre d’Études Prospectives et d’Informations Internationales (CEPII), Base pour l’Analyse du Commerce International (BACI).

^a Countries are shown in descending order according to their strength centralities in 2014, which are normalised by the total value of the foreign intermediate inputs embodied in the global (63 countries) network’s manufacturing exports. Countries with a strength centrality of less than 1% in 2014 are not shown.

The analysis by source sector shows that China’s largest out-strength centrality in Latin America (6 countries) is in Textiles, leather and footwear, which represents less than 2% of total foreign inputs. Among the main source sectors, China accounts for a larger share in Basic metals, Fabricated metal products, Computer, electronic and optical equipment, Machinery and equipment, n.e.c., and Rubber and plastics products (see table A.3 in annex 2). In all six sectors, China’s participation increased

significantly since the early 2000s, at the expense of other extraregional suppliers like the United States, the European Union and other Asian economies. Latin American countries have also been affected by China's competition in intraregional markets, particularly as a source of Basic metals and Textiles, leather and footwear.

Mexico's backward linkages with China also experienced a significant increase along the studied period, as reflected in this country's out-strength centralities (see table A.4 in annex 2). This is particularly the case of Computer, electronic and optical equipment, Electrical machinery and apparatus, n.e.c., Machinery and equipment, n.e.c., Fabricated metal products, and Rubber and plastics products, among the main source sectors. With the exception of Computer, electronic and optical equipment, where Asian countries account for over 70% of the total (compared to less than 20% in 2000), the United States remains as the main origin of foreign intermediates for Mexican manufacturing exports. Mexico's above-mentioned weak backward linkages with Latin American and Caribbean countries are largely concentrated in primary and low-technology sectors (except for Brazil, Costa Rica and Nicaragua, who also show significant linkages in some more technology-intensive industries).

Most imported intermediate goods used in the production of Asia (14 countries)'s manufacturing exports have an intraregional origin, particularly those with a higher technology content (see table A.5 in annex 2). China has also played an increasing role as a foreign input provider in this network, while countries like Japan and the United States have lost ground. However, it should be noted that a large proportion of the value added embodied in Chinese technology-intensive intermediate exports is sourced from abroad (mostly, other Asian countries, the European Union, and the United States) (Zaclicever, 2017).

The above findings reflect an asymmetric vertical integration between Latin American and Asian economies, where the formers are predominantly specialised in supplying relatively unprocessed natural resource-based inputs while importing more technology-intensive intermediates from extraregional markets (increasingly, China). Although this integration pattern is similar to that of Latin American countries with the European Union and, to a lesser extent, the United States, the asymmetry is accentuated in their relationship with Asia (particularly, China).

Countries' authority and hub centralities provide additional information on their relevance as users and suppliers of foreign intermediates, respectively, taking into consideration how important their trading partners are. In terms of authority centrality, Mexico leads within Latin America (7 countries), at great distance from the other six countries, due to its own relevance as importer and its strong linkages with the United States (a leading hub) (see figure 4.A). Also in line with countries' in-strength centrality, Brazil is largely the main authority in Latin America (6 countries), followed by Argentina and Chile—with rising authority scores—and Costa Rica—who has lost ground— (see figure 4.B). Within Asia (14 countries), China exhibits an increasingly central position, to the detriment of most other countries (including Korea, Japan, Malaysia, and Taiwan) (see figure 4.C).

Figure 4
Selected countries: authority centrality in regional networks, 2000 and 2014^a
(Scores and rank positions)

Source: Author’s calculations on the basis of input-output data from the Organisation for Economic Cooperation and Development (OECD)’s ICIO tables; and trade data from the Centre d’Études Prospectives et d’Informations Internationales (CEPII), Base pour l’Analyse du Commerce International (BACI).

^a Countries are shown in descending order according to their authority centrality in 2014. Labels indicate countries’ rank position in 2014, values for 2000 are shown in brackets.

The analysis of countries' hub scores shows that the high relevance of the United States as input supplier for Mexico —the most central importer in Latin America (7 countries)— is reflected in this country's large hub centrality (see figure 5.A). China ranks second, still far from the United States but showing a significant increase since 2000, when it ranked seventh. Nine of the twenty top-ranked hubs are Asian countries, in comparison with only two countries from Latin America (Costa Rica, ranked ninth, and Brazil, ranked twelfth). When Mexico is excluded a different picture emerges, as China ranks first (compared to eleventh in 2000) —with a similar hub score than the United States—, and Latin American countries move to more central positions (see figure 5.B and table A.6 in annex 2).¹⁰

Countries with strongest forward linkages with China —the main authority in Asia (14 countries)— exhibit larger hub centralities in that network (particularly, Korea, Japan, Taiwan, and the United States) (see figure 5.C). Also in this case, only two countries from Latin America are among the twenty top-ranked suppliers, Brazil (ranked thirteenth) and Chile (ranked fifteenth), followed by Costa Rica, Mexico, Peru, Argentina and Uruguay in lower positions (see table A.6 in annex 2). The same seven Latin American countries have the largest hub centralities in the global (63 countries) network, where Korea, the United States, Japan, Taiwan and Germany are the most central input providers (see figure 5.D).

Countries' hub scores computed at the source sector level show a similar pattern than their out-strength centralities, examined above. Latin American countries hold more central positions as providers of primary and natural resource-based manufactured intermediates, while their role as a source of more technology-intensive inputs is, with a few exceptions, not significant. As shown in diagrams 1 and 2, the number of countries from Latin America ranked in the top twenty hubs reduces as inputs' technology content increases.¹¹ Thus, while for Latin America (7 countries) seven to eleven South American and Central American countries were in 2014 among the main providers in Agriculture, Mining and quarrying and Food products, beverages and tobacco —natural resource-based sectors that account for a low share of total inputs—, only one to three of these countries (Brazil, Costa Rica, Honduras or Nicaragua, depending on the sector) had such central positions in Machinery and equipment, n.e.c., Computer, electronic and optical equipment, Electrical machinery and apparatus, n.e.c. and Transport equipment —medium-high or high-technology industries that represent a large proportion of total intermediates— (see diagrams 1.A). When Mexico is excluded, intraregional linkages become more relevant (i.e., central), although Latin American countries' hub centralities remain low in the most technology-intensive sectors, dominated by extraregional providers (see diagrams 1.B).

¹⁰ See tables A.6 and A.7 in annex 2 for complete results on Latin American and Asian countries' hub and authority centralities.

¹¹ The diagrams were created with NodeXL (<http://nodexl.codeplex.com>). Each diagram shows at the bottom all Latin American, Caribbean and Asian source countries, as well as the main hubs from other regions. Node shape identifies origin regions and subregions, as follows: Triangle: South America; Square: Mexico; Solid square: Central America; Solid diamond: The Caribbean; Disk: Asia; and Solid triangle: Rest of the world. Node size is given by countries' hub score, while labels indicate countries' rank position. The twenty top-ranked source countries in each sector are shown in blue. As for importing countries, shown in grey at the top of each diagram, they are presented in descending order according to their authority score (reflected also in node size). Sector share corresponds to the participation of each source sector in the intermediate inputs embodied in the network's exports in 2014.

Selected countries: hub centrality in regional and global networks, 2000 and 2014^a
(Scores and rank positions)

Source: Author's calculations on the basis of input-output data from the Organisation for Economic Cooperation and Development (OECD)'s ICIO tables; and trade data from the Centre d'Études Prospectives et d'Informations Internationales (CEPII), Base pour l'Analyse du Commerce International (BACI).

^a Countries are shown in descending order according to their hub centrality score in 2014. Labels indicate countries' rank position in 2014, values for 2000 are shown in brackets.

In Asia (14 countries), Latin American countries also hold more central positions in primary and natural resource-based manufacturing sectors, but the number of these countries among the twenty top-ranked suppliers is significantly lower than in Latin America (7 countries) and Latin America (6 countries). Specifically, only five Latin American economies (Argentina, Brazil, Chile, Peru, and Uruguay) were in 2014 among the top twenty hubs in such sectors, which account for a low share of total inputs (except for Basic metals) (see diagrams 2.A to 2.H). In the more relevant technology-intensive sectors, only Costa Rica (Computer, electronic and optical equipment) and Mexico (Computer, electronic and optical equipment, Electrical machinery and apparatus, n.e.c., and Transport equipment) had rather central positions in the Asian network (see diagrams 2.I to 2.L).

According to the sector-level hub scores, Asian economies are among the main input suppliers in all sectors, both in Latin America (7 countries) and Latin America (6 countries). In contrast to Latin American economies, the number of Asian countries ranked in these networks' top twenty hubs is generally larger in those sectors with a higher technology content (see diagram 1). Also, China holds increasingly central positions in most sectors, ranking in 2014 in the top five in nine of the twelve sectors considered (mostly second in Latin America (7 countries), behind the United States, and first or second in Latin America (6 countries)), compared to two of twelve in 2000.

The aforementioned dominant role of intraregional suppliers in Asia (14 countries) reflects in the fact that, in all source sectors (except for Mining and quarrying), at least seven Asian countries are among this network's top twenty hubs (see diagram 2). Countries like Japan, Korea and China play a more central role in medium-high or high-technology industries, although they are also among the main suppliers in sectors like Textiles, leather and footwear and Basic metals. In contrast, countries like India and Indonesia hold more central positions in primary and natural-resource based sectors. It should be noted that, as the main regional authority, China has a significantly less central role as a hub in Asia (14 countries) than in Latin America (7 countries) and Latin America (6 countries).

The sector-level results on countries' authority centralities shown in diagrams 1 and 2 reveal that, in all source sectors, China ranks first in Asia (14 countries) —with a substantially larger authority score than the other countries—, while in Latin America (7 countries) Mexico is largely the main authority. In both cases, the position of the other countries varies considerably across sectors, although Korea and Brazil generally rank second in their corresponding networks. In Latin America (6 countries) there are also significant differences in countries' position across sectors, even though Brazil dominates in seven of the twelve sectors (Agriculture, Textiles, leather and footwear, Chemicals and chemical products, Basic metals, Fabricated metal products, Machinery and equipment, n.e.c., and Electrical machinery and apparatus, n.e.c.), and Chile in three of them (Mining and quarrying, Food products, beverages and tobacco, and Wood, paper and printing).

B. Cluster analysis

The characterisation of countries' roles as suppliers of foreign intermediates for Latin American and Asian exports is complemented here with a cluster analysis. As described in section I, clusters are defined on the basis of the composition of countries' vertical trade-related intermediate exports, in terms of five categories of inputs: agriculture, mining, low-technology, medium-low-technology, and medium-high or high-technology.

In the case of Latin America (7 countries), the resulting 6-cluster partition shows a first cluster formed by those suppliers with a relatively large participation of medium-low-technology inputs (see figure 6.D). Countries in cluster 2 are characterised by a comparatively large share of low-technology inputs (see figure 6.C). Cluster 3 and, to a greatest extent, cluster 4 group those suppliers specialised in medium-high or high-technology inputs (see figures 6.E and 6.F). Countries in cluster 5 show a relatively large share of agricultural inputs (see figure 6.A). Finally, countries with a comparatively large participation of mining inputs are assigned to cluster 6 (see figure 6.B).

The allocation of Latin American and Caribbean suppliers in this network shows that a large number of them (17), mostly from the Caribbean, are included in one of the two clusters associated with the most technology-intensive inputs (cluster 3 or 4).¹² However, these countries are not relevant suppliers of this category of intermediates, as indicated in figures 6.E and 6.F by their low out-strength centralities (Brazil in cluster 3 and Costa Rica in cluster 4 show the largest values, with 1.6%). Most other Latin American and Caribbean countries are included in clusters 1 (7) or 2 (5) —associated with the other two categories of manufactured inputs—, also with low out-strength centralities (Chile with 1.6% and Uruguay with 0.8% have the largest metrics in their corresponding clusters).¹³ The remaining four countries are assigned to one of the “primary clusters” (5 or 6), where two of them are relevant suppliers (Paraguay in cluster 5 and Peru in cluster 6, with 6.6% and 19.7%, respectively).

As shown in figure 6, most Asian suppliers in Latin America (7 countries) are included in clusters 3 (8) or 4 (7), where China, Japan, Korea, Malaysia and Taiwan show significant levels of out-strength centrality. The central role played by the United States —assigned to cluster 3— as a hub in this network is reflected in its high relevance as a supplier of the five categories of inputs. To a lesser extent, China —the second main hub— shows high out-strength centralities in the three categories of manufactured inputs.

Clustering results for Latin America (6 countries) also show a 6-cluster partition with: 1) a first cluster characterised by a relatively large participation of medium-low-technology inputs (see figure 7.D); 2) two clusters (2 and 4) formed by those suppliers specialised in medium-high or high-technology inputs (see figures 7.E and 7.F); 3) one cluster (3) that groups countries with a comparatively large share of low-technology inputs (see figure 7.C); 4) one cluster (5) formed by

¹² Labels in figures 6 to 8 identify the Latin American and Asian countries assigned to the cluster characterised by the corresponding input category, whose members are shown in red (e.g., in figure 6.A, cluster 5, associated with agricultural inputs). For a complete list of the countries assigned to each cluster see table A.8 in annex 2.

¹³ It should be noted that Argentina and Colombia, with a similar participation of medium-low-technology and medium-high or high-technology inputs, lie between clusters 1 and 3 (with low levels of out-strength centrality in both categories of inputs).

countries that show a relatively large participation of agricultural inputs (see figure 7.A); and 5) one last cluster (6) that encompasses those suppliers with a comparatively large share of mining inputs (see figure 7.B).

The comparison with Latin America (7 countries) does not show major differences in terms of the allocation of Latin American and Caribbean suppliers. A somewhat smaller number of these countries (14) are included in those clusters associated with the most technology-intensive inputs, where only Brazil is a relevant supplier. Argentina, Chile and Mexico (cluster 1), Bolivia (P.S. of) and Ecuador (cluster 3), Paraguay (cluster 5), and Peru (cluster 6) are the only other Latin American countries with significant levels of out-strength centrality (i.e., at least 1%) in their corresponding input categories. As for Asian suppliers, the main difference with Latin America (7 countries) relates to China, who shows a slight concentration of its vertical trade-related intermediate exports in medium-low-technology products (being therefore included in cluster 1, but actually lying between clusters 1 and 2).

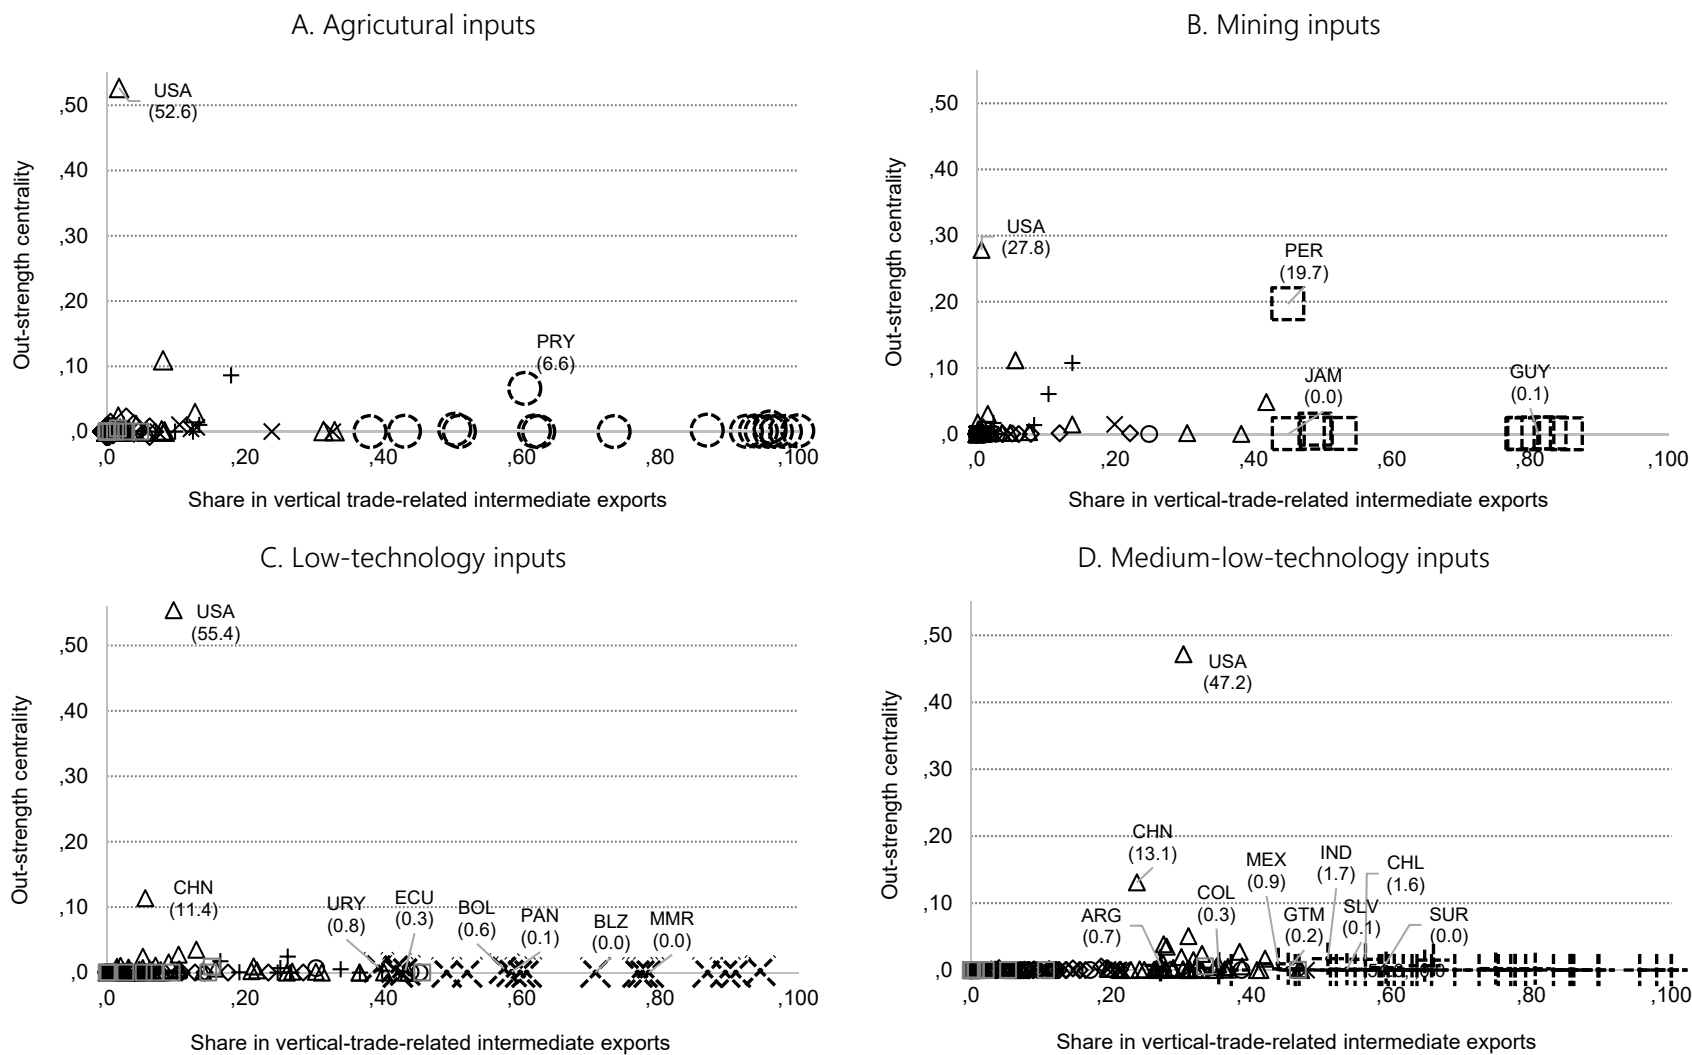

For Asia (14 countries), the clustering process results in a 5-cluster partition (see figure 8). Cluster 1 is formed by suppliers with a relatively large participation of medium-low-technology inputs (see figure 8.D). Countries in cluster 2 show a relatively large share of agricultural inputs (see figure 8.A). Countries assigned to cluster 3 are characterised by a comparatively large participation of low-technology inputs (see figure 8.C). Cluster 4 groups those suppliers with a relatively high share of mining inputs (see figure 8.B). Finally, countries with a comparatively large participation of medium-high or high-technology inputs are assigned to cluster 5 (see figure 8.E). This last cluster includes China, Japan, Korea, Taiwan and the United States—the main hubs in Asia (14 countries)—as well as most other Asian countries. In contrast, most Latin American and Caribbean suppliers (20) are assigned to the clusters associated with primary or low-technology inputs (three to cluster 2, fourteen to cluster 3, and three to cluster 4).

As shown in figure 8, most Asian countries in cluster 5 play a significant role as suppliers of medium-high or high-technology inputs (particularly, Japan, Korea, China, and Taiwan), while the Latin American and Caribbean countries in this cluster have very low levels of out-strength centrality (Costa Rica shows the largest value, with 1.2%, followed by Mexico with only 0.4%). Likewise, most Latin American and Caribbean countries assigned to the other four clusters also account for a very low portion of the corresponding input category; the exceptions are Brazil in cluster 2 (20.3%) and, to a lesser extent, Peru in cluster 4 (4.1%), Chile in cluster 1 (2.9%), and Argentina in cluster 3 (1.3%).

The above results illustrate the asymmetric nature of the vertical trade relations between Latin America and Asia, already pointed out in section A. They also show the weak intraregional linkages that, in contrast to Asian economies, characterise Latin American and Caribbean countries (particularly in the most technology-intensive sectors).¹⁴ A complementary product-level analysis of countries' export similarities—beyond the scope of this document—would provide a deeper characterisation of their roles as suppliers of each category of inputs.

¹⁴ Although this network-level analysis hides some relevant bilateral linkages (e.g., Argentina's backward integration with Brazil), Latin American and Caribbean countries are characterised by lower levels of intraregional vertical integration than countries in other regions (Cadestin et al., 2016; Zaclivever, 2017).

III. Concluding remarks

Network analysis techniques offer a powerful means for studying the connections between countries within international production networks. This document adopts a network analysis approach to examine the vertical trade relations between Latin America and Asia, showing the potential of these techniques for providing new insights into the patterns and dynamics of countries' GVC linkages. Particularly, network-based measures are used to assess how important countries are as users and suppliers of foreign intermediate inputs in each network, at both the aggregate and sector level. In addition, clustering techniques are applied to identify groups of supplier countries.

The analysis shows the expansion experienced by Latin America-Asia vertical integration between 2000 and 2014. Particularly, it highlights the increasingly central role played by China, both as a user of inputs imported from Latin American countries and as a supplier of intermediates for these countries' exports. The document also shows the asymmetric nature of the linkages between the two regions, where Latin America is largely specialised in supplying primary and relatively low-technology manufactured inputs while importing more technology-intensive intermediates. Overall, Latin American economies do not play a relevant role as suppliers of foreign intermediates for Asian exports and show significantly weaker intraregional linkages than Asian countries.

For Latin American countries to become more relevant partners for China and other Asian economies, and maximise the positive spillovers associated with international production integration, the region needs to diversify and upgrade its participation in GVCs. This would require coordinated plans across a number of policy areas, including trade, foreign direct investment, innovation and human capital formation (Zaclicever, 2017).

The availability of comprehensive inter-country input-output data for Latin American economies (and their partner countries) would allow the use of network measures computed from

data on trade in value added. This would provide a better characterisation of countries' roles in each network, by revealing their actual contribution to the value generated in each stage of the production process. It would also allow capturing the complete set of direct and indirect interconnections amongst participating countries.

Annexes

Annex 1

Vertical trade data

The construction of the bilateral intermediate trade database used in this document starts by computing the direct and indirect import content of countries' gross manufacturing exports, given by:

$$\mathbf{VS}_{c,t} = \mathbf{A}_{c,t}^M (\mathbf{I} - \mathbf{A}_{c,t}^D)^{-1} \hat{\mathbf{E}}_{c,t} = \mathbf{A}_{c,t}^M \mathbf{L}_{c,t} \hat{\mathbf{E}}_{c,t} \quad (\text{A.1})$$

where the subscripts c and t denote country and time, respectively; $\mathbf{A}_{c,t}^M$ is the $K \times K$ matrix of direct imported input coefficients; $\mathbf{A}_{c,t}^D$ is the $K \times K$ matrix of direct domestic input coefficients (or technical coefficients); \mathbf{I} is a $K \times K$ identity matrix; $\mathbf{L}_{c,t} = (\mathbf{I} - \mathbf{A}_{c,t}^D)^{-1}$ is the $K \times K$ Leontief inverse; $\hat{\mathbf{E}}_{c,t}$ is a $K \times K$ diagonal matrix of gross manufacturing exports by exporting industry; and K is the number of industries.¹⁵

Each $\mathbf{VS}_{c,t}(i, j)$ (i.e., each component of matrix $\mathbf{VS}_{c,t}$) gives the value of the imported inputs from industry i used in country c at time t in the production of industry j 's gross exports. Thus, the imported intermediates from industry i embodied in country c 's total gross manufacturing exports is calculated as:

$$\mathbf{VS}_{c,t}(i) = \sum_j \mathbf{VS}_{c,t}(i, j) \quad (\text{A.2})$$

The data used to compute $\mathbf{VS}_{c,t}$ come from the OECD's ICIO tables, which provide information with a 34-industry breakdown (see table A.1).

The final step in the construction of the bilateral trade database is the disaggregation of $\mathbf{VS}_{c,t}(i)$ by origin country:

$$\mathbf{VS}_{p,c,t}(i) = \mathbf{VS}_{c,t}(i) * \mathbf{m}_{p,c,t}(i) \quad (\text{A.3})$$

where $\mathbf{m}_{p,c,t}(i)$ is the share of origin country p in country c 's total imports of intermediate inputs from industry i at time t .¹⁶ This share is computed using 6-digit Harmonized System (HS) level data from BACI.¹⁷ The correspondence between industries and HS codes considered here is based on the conversion tables used in the construction of the OECD's ICIO tables. This ensures a good match between the product-level bilateral trade data and the industry of origin in $\mathbf{VS}_{c,t}(i)$.

¹⁵ Each coefficient of matrix $\mathbf{A}_{c,t}^D$, $a_{c,t}^D(i, j)$, gives the value of products from domestic industry i used by industry j as intermediate inputs to produce one monetary unit of output. Similarly, each coefficient of matrix $\mathbf{A}_{c,t}^M$, $a_{c,t}^M(i, j)$, shows the imported inputs from foreign industry i required by domestic industry j to produce one monetary unit of output. For details on these matrices see Ahmad et al. (2017).

¹⁶ $\mathbf{m}_{p,c,t}(i) = \frac{M_{p,c,t}(i)}{\sum_p M_{p,c,t}(i)}$ where $M_{p,c,t}(i)$ are the intermediate inputs from industry i imported by country c from country p at time t .

¹⁷ BACI provides bilateral values and quantities of exports, reconciling exporting and importing countries' data from the United Nations Commodity Trade Statistics Database (COMTRADE) (see Gaulier and Zignago, 2010).

^a Countries included in the Organisation for Economic Cooperation and Development (OECD)'s ICIO tables are indicated by asterisks.

^b Due to data availability reasons, Belgium and Luxembourg are considered as a single country.

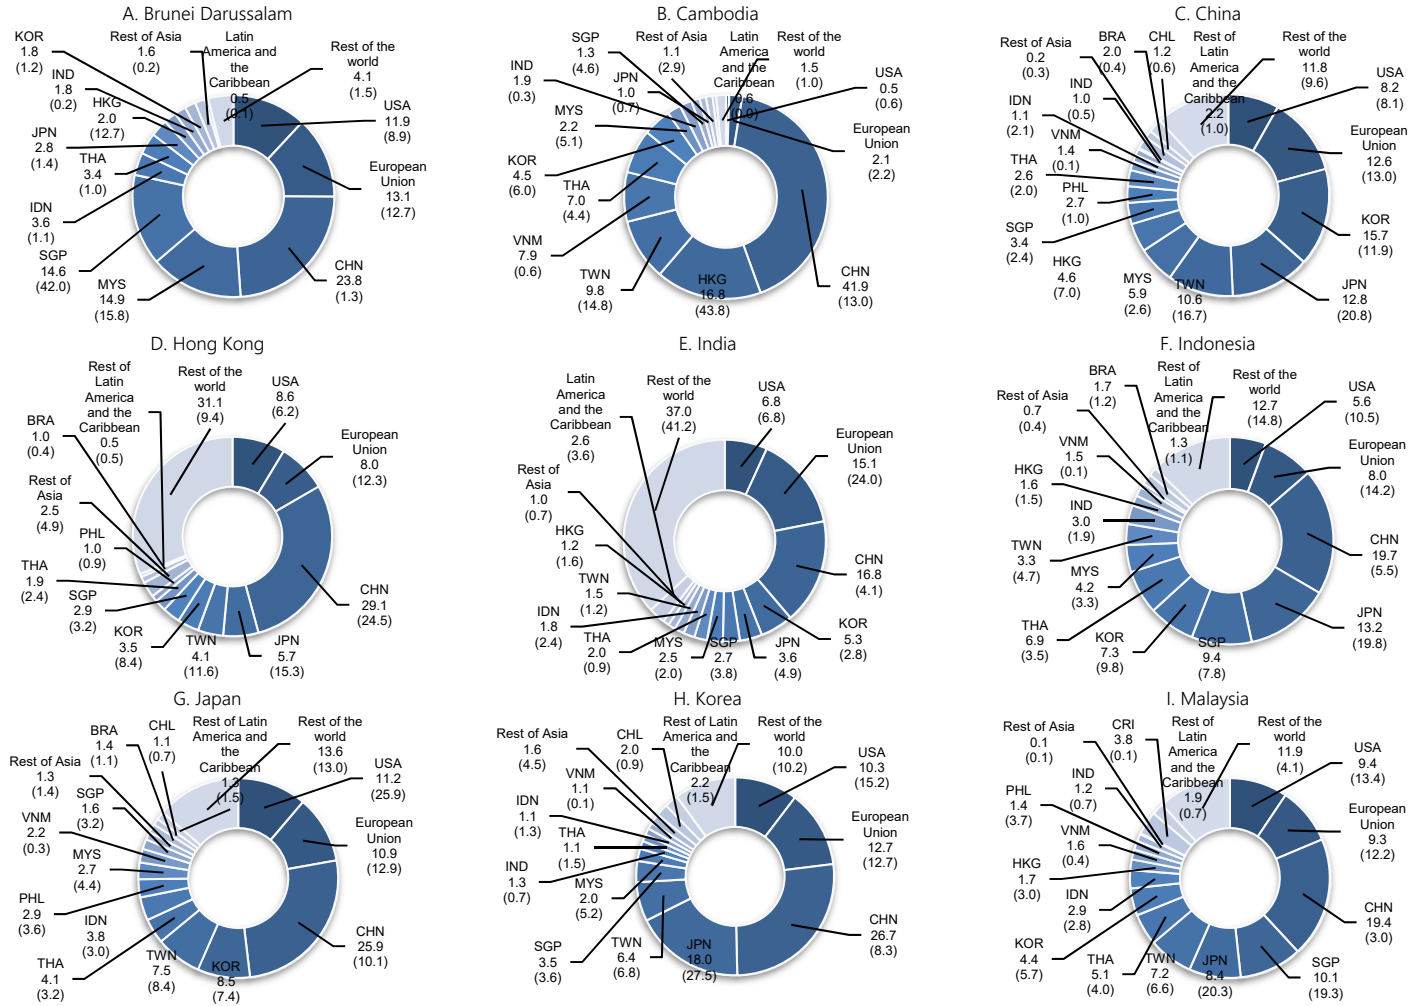

Figure A.1
Latin America (7 countries): imported inputs embodied in gross manufacturing exports by geographical origin, 2000 and 2014^a
(Percentages of the total)

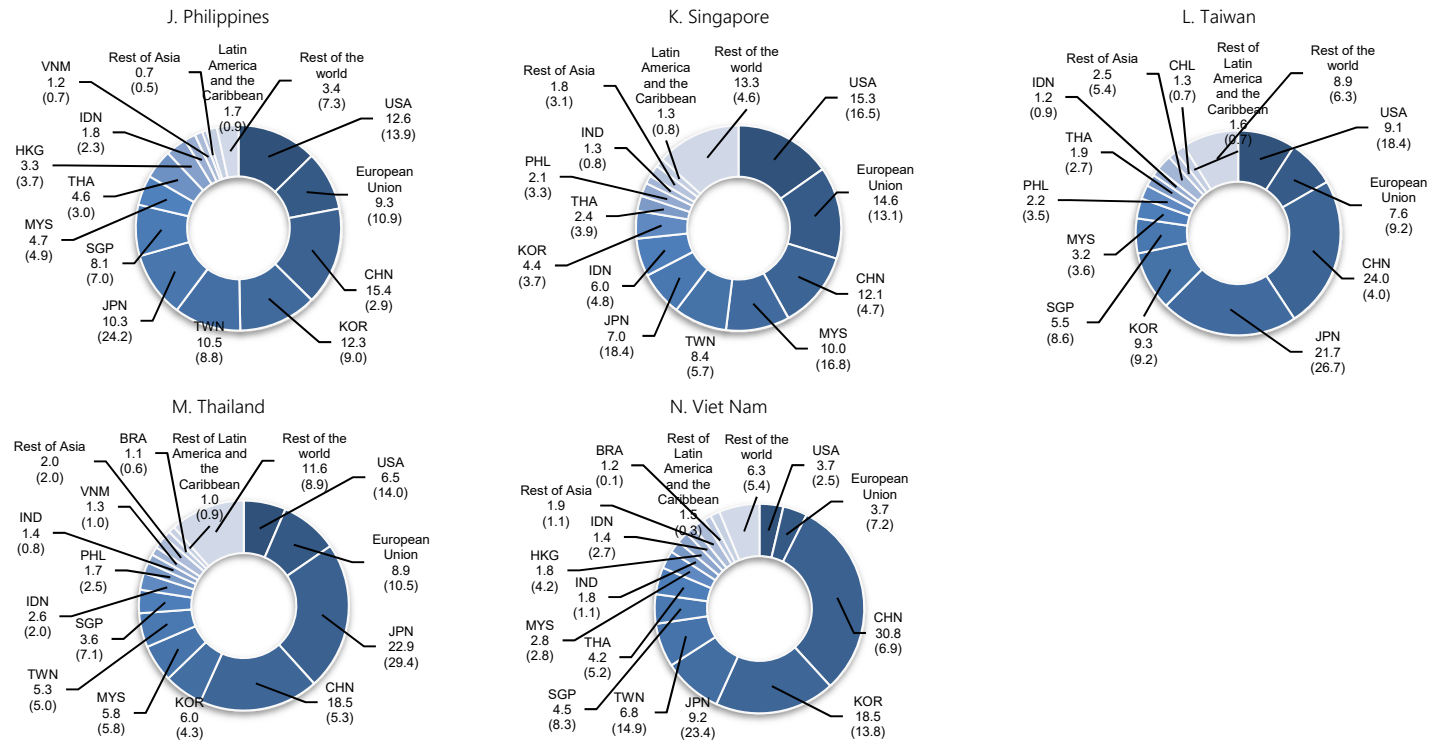

Source: Author's calculations on the basis of input-output data from the Organisation for Economic Cooperation and Development (OECD)'s ICIO tables; and trade data from the Centre d'Études Prospectives et d'Informations Internationales (CEPII), Base pour l'Analyse du Commerce International (BACI).

^a Percentages in brackets indicate the share of each origin in 2000.

Figure A.2
Asia (14 countries): imported inputs embodied in gross manufacturing exports by geographical origin, 2000 and 2014^a
(Percentages of the total)

Source: Author's calculations on the basis of input-output data from the Organisation for Economic Cooperation and Development (OECD)'s ICIO tables; and trade data from the Centre d'Études Prospectives et d'Informations Internationales (CEPII), Base pour l'Analyse du Commerce International (BAC).

^a Percentages in brackets indicate the share of each origin in 2000.

Table A.3
Selected countries and regions: out-strength centrality in Latin America (6 countries) by origin sector,
2000 and 2014^{a,b}

Source: Author's calculations on the basis of input-output data from the Organisation for Economic Cooperation and Development (OECD)'s ICIO tables; and trade data from the Centre d'Études Prospectives et d'Informations Internationales (CEPII), Base pour l'Analyse du Commerce International (BACI).

^a Latin America (6 countries) includes Argentina, Brazil, Chile, Colombia, Costa Rica and Peru.

^b The numbers in brackets at the top of each column correspond to the share of each sector in the foreign intermediate goods embodied in Latin America (6 countries)'s manufacturing exports in 2014. For a description of sector codes see table A.1.

Table A.4
Selected countries and regions: out-strength centrality in Mexico by origin sector, 2000 and 2014^a

Source: Author's calculations on the basis of input-output data from the Organisation for Economic Cooperation and Development (OECD)'s ICIO tables; and trade data from the Centre d'Études Prospectives et d'Informations Internationales (CEPII), Base pour l'Analyse du Commerce International (BACI).

^a The numbers in brackets at the top of each column correspond to the share of each sector in the foreign intermediate goods embodied in Mexico's manufacturing exports in 2014. For a description of sector codes see table A.1.

Table A.5
Selected countries and regions: out-strength centrality in Asia (14 countries) by origin sector, 2000 and 2014^a

Source: Author's calculations on the basis of input-output data from the Organisation for Economic Cooperation and Development (OECD)'s ICIO tables; and trade data from the Centre d'Études Prospectives et d'Informations Internationales (CEPII), Base pour l'Analyse du Commerce International (BACI).

^a Score represents the value of countries' hub and authority centralities, while ranking indicates their corresponding position.
