

ECONOMIC SURVEY OF LATIN AMERICA 1955

including an essay on
GOVERNMENT INCOME AND EXPENDITURE
1947-1954

*Prepared by the secretariat
of the Economic Commission for Latin America*

UNITED NATIONS
Department of Economic and Social Affairs
New York, 1956

E/CN.12/421/Rev.1

May 1956

UNITED NATIONS PUBLICATION

Sales No.: 1956. II.G. 1

Price: \$U.S. 2.00; 14/- stg.; Sw. fr. 8.50
(or equivalent in other currencies)

EXPLANATION OF SYMBOLS

The following symbols have been used throughout this *Survey*:

Three dots (...) indicate that data are not available or are not separately reported

A dash (—) indicates that the amount is nil or negligible

A minus sign (–) indicates a deficit or decrease

A full stop (.) is used to indicate decimals

A comma (,) is used to distinguish thousands and millions

A slash (/) indicates a crop year or fiscal year, e.g., 1954/55

Use of a hyphen (-) between dates representing years, e.g., 1950-1954, normally signifies an annual average for the calendar years involved, including the beginning and end years. "To" between the years indicates the full period, e.g., 1950 to 1954 means 1950 to 1954, inclusive

References to "tons" indicate metric tons, and to "dollars" United States dollars, unless otherwise stated

The term "billion" signifies a thousand million

Details and percentages in tables do not necessarily add to totals, because of rounding

TABLE OF CONTENTS

INDEX OF TABLES.....	Page ix
INDEX OF FIGURES.....	xiii

PART I

Economic trends in Latin America during 1955

CHAPTER I. ECONOMIC DEVELOPMENT TRENDS IN LATIN AMERICA

I. General trends	3
1. Rate of growth	3
2. External demand, aggregate demand and the rate of growth.....	4
3. The capacity to import and the balance of payments.....	5
4. The external sector and investment.....	6
5. The composition of imports and the investment coefficient.....	7
6. The relative inadequacy of saving and the investment coefficient.....	8
7. The product-capital ratio.....	9
II. Trends in selected countries.....	9
1. Argentina	9
2. Brazil	13
3. Colombia	15
4. Mexico	18
Appendix to Chapter I.....	20

CHAPTER II. FOREIGN TRADE AND THE BALANCE OF PAYMENTS

I. Introduction	22
II. The balance of payments.....	23
1. Trends in the current account of the balance of payments.....	24
2. Trends in the capital account and new foreign investment.....	27
3. The balance-of-payments situation and financing methods.....	29
III. Trade and exchange policy in Latin America.....	30
1. Brazil	31
2. Colombia	32
3. Ecuador	33
4. Argentina	33
5. Uruguay	34
6. Chile	34
7. Peru	34
8. Mexico	35

CHAPTER III. AGRICULTURE

I. General aspects and problems.....	37
1. Production trends	37
2. World market prices and surpluses.....	39

	<i>Page</i>
II. The main commodities.....	42
1. Wheat	42
2. Maize	45
3. Rice	46
4. Sugar	47
5. Coffee	49
6. Cotton	52
7. Meat	55
8. Wool	56
 CHAPTER IV. INDUSTRY	
I. Over-all trends in production.....	58
II. Outstanding events in Latin America's industry.....	59
III. Development by sectors.....	60
1. Foodstuffs and beverages.....	60
2. Tobacco products	61
3. Textiles	61
4. Footwear and clothing.....	62
5. Pulp and paper.....	63
6. Chemical and pharmaceutical products.....	64
7. Rubber manufactures	65
8. Cement, glass and ceramic products.....	66
9. Iron and steel.....	67
10. Transforming industry for iron and other metals.....	68
 CHAPTER V. MINING	
1. Recent events and trends.....	70
2. Copper	70
3. Tin	73
4. Lead and zinc.....	74
5. Iron ore	74
6. Bauxite	76
7. Sulphur	76
 CHAPTER VI. ENERGY	
1. Introduction	78
2. The pattern of consumption.....	78
3. Production and consumption of petroleum and its derivatives.....	82
4. Production and consumption of electric energy.....	86
5. The substitution process within the energy sector.....	88
6. Petroleum and the exchange budget.....	89
7. The evolution and financing of energy investment.....	90
8. Investment in electricity and petroleum.....	91
9. Plans for developing energy resources.....	96
10. Institutional development	97
 APPENDIX. THE MECHANICAL WOODWORKING INDUSTRIES	
I. General considerations	99
II. The sawmills	99
III. The plywood industry.....	104
IV. The fibreboard and chipboard industry.....	106
V. Conclusions	106

PART II

Government income and expenditure 1947-1954

INTRODUCTION	111
CHAPTER I. PUBLIC EXPENDITURE	
I. Distribution of public expenditure by administrative levels.....	113
II. The growth of public expenditure.....	115
III. The composition of current expenditure.....	118
IV. The nature and evolution of transfer payments.....	121
V. Public investment	123
VI. Public expenditure in relation to the whole national economy.....	127
CHAPTER II. FISCAL INCOME	
I. The tax structure of Latin America.....	131
1. The over-all tax burden.....	131
2. Importance of tax revenues from the external sector.....	132
3. Relative importance of direct and indirect taxes.....	137
II. Income tax	140
1. Introduction	140
2. Taxation on personal income.....	142
3. Taxes on business enterprises and incentives to investment.....	140
CHAPTER III. PUBLIC SAVINGS AND DEFICIT FINANCING	
I. Introduction	152
II. Government savings	153
III. Budget deficits	157
IV. The mechanism of deficit financing.....	160
V. The public debt and its financing.....	162
1. The internal debt.....	163
2. The external debt.....	165
CHAPTER IV. EXCHANGE POLICY AS A FISCAL INSTRUMENT	
I. Fiscal aspects of exchange policy.....	169
II. Analysis by countries.....	169
1. Chile	170
2. Venezuela	171
3. Brazil	172
4. Argentina	174
5. Other countries	176

IMPORTANT NOTE

Many of the figures for 1955 should be considered purely provisional and subject to corrections which in some cases may be of considerable significance. The figures for the gross product and its components used in chapter I, Part I differ from the estimates contained in previous surveys. These discrepancies are due to the fact that new and revised statistics have been received from the countries concerned. The modifications relating to Argentina and Brazil are particularly important.

Index of tables

PART I

<i>Table</i>	<i>Page</i>
<i>Chapter I</i>	
1. Latin America: Growth in 1945-55.....	3
2. Latin America: Annual rates of per capita growth, 1945-55.....	3
3. Latin America: Annual rates of growth of per capita gross income in selected countries, 1945-55	4

54. Latin America: Production indices for pulp and paper.....	63
55. Latin America: Production of pulp, paper and board.....	64
56. Latin America: Paper and board consumption, 1954-55.....	64
57. Latin America: Production of fertilizers, sulphuric acid and caustic soda, 1955	65
58. Latin America: Production indices for rubber manufactures.....	65
59. Latin America: Production of tyres and inner-tubes for motor vehicles.....	65
60. Latin America: Production indices for cement, glass and ceramic products....	66
61. Latin America: Production and consumption of cement.....	66
62. Latin America: Production of plate glass.....	67
63. Latin America: Production of pig-iron, steel ingot and rolled products.....	67

Chapter V

64. Copper exports and re-exports to the centrally planned economies, by type of product and country, 1953-55.....	71
65. Latin America: Mine production and consumption of copper, 1951-55.....	72
66. Estimated world copper production, capacity at new mines and mines undergoing expansion programmes, 1955-58.....	73
67. Latin America: Mine production and consumption of tin.....	73
68. Latin America: Mine production and consumption of lead.....	75
69. Latin America: Mine production and consumption of zinc.....	75
70. Latin America: Production and consumption of iron ore.....	76
71. Latin America: Production and consumption of bauxite.....	77
72. Latin America: Bauxite reserves.....	77
73. Latin America: Production of native sulphur.....	77

Chapter VI

74. Latin America: Gross consumption of total energy and electricity production...	79
75. Latin America: Gross consumption of commercial energy and aggregate electricity production	80

<i>Table</i>	<i>Page</i>
76. Argentina: Gross consumption of energy by economic sectors, 1954.....	81
77. Brazil: Gross consumption of energy by economic sectors, 1955.....	82
78. Latin America: Crude oil situation.....	83
79. Latin America: Foreign trade in crude oil and derivatives.....	84
80. Latin America: Consumption of petroleum derivatives.....	84
81. Latin America: Consumption of petroleum derivatives in annual rates of growth	85
82. Latin America: Electricity production for public service.....	86
83. Latin America: Installed capacity of electric power plants.....	87
84. Latin America: Coal situation.....	88
85. Latin America: Incidence of fuels on the value of all imports in selected countries	90
86. Latin America: Total investment in energy for domestic supply, 1955.....	90
87. Latin America: Electricity enterprises financed mainly from public funds.....	92
88. Latin America: Electricity companies financed by foreign private funds.....	94

Appendix

I. Latin America: Sawmills in selected countries according to annual capacity....	100
II. Latin America: Production and trade in sawnwood.....	100
III. Per capita sawnwood consumption in selected countries.....	101
IV. Latin America: Plywood plants.....	104
V. Latin America: Plywood production and exports.....	105

PART II

Chapter I

1. Latin America: Public expenditure distributed by government levels in selected countries	113
2. Latin America: Indices of the growth of public expenditure at constant prices...	115
3. Latin America: Per capita public expenditure in selected countries.....	116
4. Latin America: Per capita public expenditure, 1953.....	116
5. Latin America: Public expenditure as a percentage of the gross national product in selected countries.....	117
6. Latin America: Distribution of public expenditure within the central government	117
7. Latin America: Distribution of current expenditure.....	119
8. Latin America: Population employed in public administration.....	119
9. Latin America: Current expenditure in selected countries.....	120
10. Latin America: Direct transfer payments by the central government in selected countries	121
11. Latin America: Per capita transfer payments in selected countries.....	123
12. Latin America: Real investment by central governments in selected countries...	125
13. Latin America: Direct investment by central governments in selected countries..	126
14. Latin America: Gross investment and financing of private investment by the central government in selected countries.....	129

Part I

**ECONOMIC TRENDS IN LATIN AMERICA
DURING 1955**

Chapter 1

ECONOMIC DEVELOPMENT TRENDS IN LATIN AMERICA

I. GENERAL TRENDS

1. RATE OF GROWTH

The recovery in per capita gross income which had set in during the previous year continued in 1955 with an increment of 1.1 per cent. In order to assess the significance of this increase, it should be recalled that, after two years of depression, per capita income had risen by 5

per cent as a result of the vigorous reaction that took place in 1954. The 1.1 per cent expansion achieved in 1955, although comparing unfavourably with the initial impulse that preceded it, shows that the recovery persisted and represented a cumulative annual rate of about 3 per cent in relation to 1953. (See tables 1 and 2, and figure I). In 1955, the absolute level of total income was thus 48 billion dollars at 1950 prices.

Table 1. Latin America: Growth in 1945-55
(Billions of dollars at 1950 prices)

Year	Gross product	Gross income	Consumption	Investment	Available goods and services	
					As a percentage of the total	
					Consumption	Investment ^a
1945	29.8	26.8	22.7	3.6	86.2	13.8
1946	32.2	30.1	24.5	5.0	83.1	16.9
1947	34.0	32.2	26.5	6.7	79.8	20.2
1948	36.1	34.3	27.5	7.3	78.9	21.1
1949	37.2	35.6	29.4	6.5	81.9	18.1
1950	39.0	38.3	31.4	6.4	83.0	17.0
1951	41.1	40.6	33.9	7.5	81.9	18.1
1952	42.2	41.1	34.3	8.0	81.2	18.8
1953	43.2	42.3	35.0	7.1	83.1	16.9
1954	45.9	45.6	37.6	8.2	82.1	17.9
1955	48.2	47.2	39.4	8.3	82.6	17.4

Investment in fixed capital.....	5.0	8.0	-2.0	2.5	0.5

Sources: See appendix to this chapter.

These statements are supported by the fact that some of the features characterizing the years of income recovery could be observed in 1955. The influence of the external sector followed much the same lines as in the preceding year, except that it was exerted through the volume of goods and services exported rather than through the terms of trade. The latter, though similar to those prevailing in 1950 when prices were high, deteriorated in 1955; but this development was offset by an increase in exports, thanks to which Latin America as a whole was able to maintain its supplies of imported goods, without as a rule incurring undue pressure on the balance of

payments. Only four countries showed acute disequilibria in their foreign accounts.

But the region's over-all recovery obscures the disparities to be noted in some of the larger countries. In Argentina, income has pursued a slow upward trend since 1953, but has not yet regained the per capita levels of 1950 and 1951. For Brazil, the year 1955 represented a pause in the rapid process of growth registered during the immediate past. Per capita income in Colombia contracted. In Mexico, there was a continuance of the intensive economic development that had succeeded a temporary interrup-

Figure I

(Billions of dollars at 1950 prices)
Natural scale

tion in 1953, and the same was true of Venezuela. Similarly, Chile witnessed a reaction from the decline suffered by per capita gross income in 1954; while in Cuba, income figures, though not as low as in 1953 and 1954, remained far below their 1952 level. (See table 3.)

Table 3. Latin America: Annual rates of growth of per capita gross income in selected countries, 1945-55
(Percentages)

^a 1947-1955.

2. EXTERNAL DEMAND, AGGREGATE DEMAND AND THE RATE OF GROWTH

As already pointed out, the general movement towards recovery is linked with the behaviour of the external sec-

tor. Its principal determinant in 1954 was the improvement in the terms of trade, which not only raised the level of aggregate demand in the Latin American economy, but at the same time, in conjunction with the higher imports, caused gross income and available services to expand more rapidly than the gross product. (See again table 1.) This exemplified the typical process whereby the terms of trade effect, when favourable, impinge upon the internal economies of the Latin American countries and pervade every aspect of their economic life.

In 1955, the behaviour of the external sector produced similar results, but the roles of its essential components altered. Although the terms of trade remained very close to the 1950 level, their influence determined a loss of income in relation to the preceding year. On the other hand, this loss was fully offset by the larger volume of goods and services exported.

External demand therefore remained the principal factor in the recovery and promoted intensive activity in export sectors, which led to an increase in their gross product. The maintenance of income and demand in these sectors redounded to the benefit of those producing for the domestic market, as well as to that of total demand. (See figure II.)

Figure II
LATIN AMERICA: EXPORTS, IMPORTS AND THE CAPACITY TO IMPORT

(Billions of dollars at 1950 prices)
Natural scale

It was in this way that the external sector influenced the region's economic life in 1955. The difference between the incentives it provided in 1954 and 1955, respectively, must now be examined. In both cases, it was responsible for a high level of internal activity and an increment in per capita income. But while in 1954 the incentives and gains deriving from the favourable terms of trade did not give rise to additional productive efforts channelled towards the world market, the expansion of sales in 1955 meant that more resources were absorbed by export sectors and that both the rate of growth of per capita gross income and the capacity to import were thus maintained. In other words, in 1955 the economy of Latin America as a whole had to resort to heavier exports without achieving much more than a preservation of the *status quo*.

Developments in 1955 represented a weak reaction from the downward trend followed by the export coefficient in previous years. Although this coefficient still remained only a little more than 16 per cent of the gross product, and was far from regaining its high post-war level, the year 1955 was characterized by an almost universal anxiety to encourage exports, which, in absolute terms, attained their peak volume. It is generally agreed that a permanent increase in the capacity to import can better be achieved by this means than by complete dependence upon so uncertain and hazardous a process as an improvement in the terms of trade. It must be borne in mind, however, that the degree to which Latin America's exports can be absorbed by the world market is determined in the case of raw materials by the state of economic activity in the more highly-developed countries

and, in that of foodstuffs, by the low income-elasticity of world demand.

3. THE CAPACITY TO IMPORT AND THE BALANCE OF PAYMENTS

Latin America frequently encounters the difficulty that its aggregate capacity for external payment is insufficient to finance imports and the servicing of foreign capital. The propensity to import is very marked, both on account of the urgent need to purchase capital goods, raw materials and fuels on the world market and because of the high income-elasticity of demand for manufactured consumer goods, particularly those of a durable nature. Over the short term, these circumstances tend to impose a certain degree of rigidity on imports, sustaining them for some time at a high level even when the terms of trade are deteriorating and there is a consequent contraction of the capacity to import. Among the factors determining the extent of the resultant disequilibrium in the balance of payments is the evolution of the export volume. Its considerable expansion in 1955 almost entirely offset the trend towards an imbalance.

The terms of trade deteriorated in 1955 by 7 per cent in relation to the preceding year, the result being a loss of 560 million dollars. Combined with the net liabilities on movements of capital and financial services, this adverse effect would have considerably reduced the capacity to import, had not an increment to the value of 580 million dollars been registered in the volume of goods and services exported. As it was, the capacity to import decreased by only 30 million dollars. (See tables 4 and 5.)

Table 4. Latin America: Indices of the terms of trade by selected groups of countries, 1945-55

Similarly, the unfavourable influence of the terms of trade on gross income was offset by increases of more than 3 per cent and 1.1 per cent in the total and the per capita gross product, respectively. This maintenance of aggregate demand exerted the same sort of pressure on imports as in 1954, and the value of purchases abroad increased by 160 million dollars at 1950 prices. This evolution of imports and of the capacity to import meant that in 1955 the deficit in the external accounts of the region as a whole was estimated at only 50 million dollars at 1950 prices. But it should be remembered that a

favourable balance of 140 million dollars had been registered in 1954.

Latin America's aggregate balance-of-payments situation in fact conceals divergent trends among the individual countries. In four of these in particular—Argentina, Bolivia, Colombia and Uruguay—the disequilibrium in their balance of payments attained substantial proportions, and largely accounted for the region's negative balance, such as it was. Indeed, the aggregate balance-of-payments deficit of these four countries amounted to 450 million dollars at current prices, whereas for the

remainder a favourable net balance of 360 millions (also at current prices) was recorded.

Latin America's monetary reserves increased by about 160 million dollars at current prices, or by 390 millions if the same four countries are excluded from the calculation. The region's foreign trade indebtedness rose by 251 million dollars (at current prices) and by only 7 millions if the four countries in question are disregarded.

4. THE EXTERNAL SECTOR AND INVESTMENT

For the sake of simplicity, no account has hitherto been taken of the investment coefficient,¹ whose importance for economic development goes without saying. In Latin America the volume of total investment is extremely sensitive to incentives from abroad, reflecting both direct and indirect influences.

Whenever Latin America has reaped the benefits of a considerable improvement in the terms of trade, the tendency has been to maintain a high volume of gross investment, thanks to the substantial profits accruing to entrepreneurs and the greater incentives provided by the rise in total demand. (See figure III.) This stimulus was lacking in 1955, but its place was taken by the larger volume of exports, while profits and aggregate demand must also have increased. It should be recalled that the proportion of Latin America's total demand deriving from foreign sources has sometimes exceeded 20 per cent. Apart from its quantitative importance, such demand has already been shown in previous ECLA studies to be one of the principal dynamic forces affecting the internal economy. The influence on gross investment thus directly exerted by the external sector is reinforced by its effect on the capacity to import, where any increase facilitates greater imports of capital goods.

Trends of this kind were apparent in 1954 and 1955. In the former year, gross investment in fixed capital rose from 7.0 to 7.4 billion dollars (at 1950 prices), that is,

¹ Ratio between gross investment in fixed capital and available goods and services.

by about 6 per cent. In 1955 it increased to 7.6 billion dollars, which represented an increment of less than 3 per cent. Thus, in both years the provision of incentives by the external sector and the maintenance of a high capacity to import coincided with an increased volume of gross investment. But, since the value of available goods

Figure III

LATIN AMERICA: INDICES OF THE TERMS OF TRADE, GROSS INVESTMENT AND THE PRODUCT-CAPITAL RATIO

Natural scale

and services rose from 45.8 billion to 47.7 billion dollars (at 1950 prices), in 1954 the investment coefficient was almost 2 per cent below that of 1953, while in 1955 it was lower than in both these years. The rate of capital

formation therefore weakened, despite the increase in available goods and services. Moreover, the investment coefficient has shown a downward trend since 1952. (See table 6.)

^a As a percentage of total available goods and services.

If the inertia of the investment coefficient were to persist over the long term, it would constitute a serious obstacle to an acceleration of Latin America's economic development.

5. THE COMPOSITION OF IMPORTS AND THE INVESTMENT COEFFICIENT

In view of the problem created for Latin America by this trend in the investment coefficient, it would be well to identify the factors hindering its growth. One of the chief obstacles, as a general rule, is the inadequacy of the capacity to import. In recent years—even in 1955, when the region was able to import a substantial volume of goods—the possibilities for larger purchases of capital goods have not improved, since the capacity to import had to be used to meet urgent raw-material and fuel requirements; otherwise, over-all economic activity would have suffered over the short term for want of supplies. Consequently, import policy was inevitably based on the trend to maintain purchases of capital goods at a high level without unduly cutting down supplies of goods essential to industry.

Between 1945 and 1952, Latin America pursued a policy deliberately designed to foster the rapid progress of industrialization—and with it a growth of the economy characterized by greater diversity of production—as an effective means of absorbing under-employed labour surpluses and of raising income levels. Larger sums were invested in basic social capital; monetary and credit policy was planned to promote the expansion of industry, its due correlation with agriculture at times being neglected; and trade policy aimed at the replacement of imports by domestically-produced goods, whose manufacture was correspondingly encouraged. Advantage was thus taken of the steady improvement in the terms of trade and full use was made of the monetary reserves accumulated during the war.

In 1952, the share of the consumer goods in total imports was considerably lower, and that of capital goods higher, than in 1945. But, in face of the marked increase in imports, specific restrictions were already beginning to be imposed by 1952, in which year purchases abroad were, nevertheless, 10 per cent in excess of the total capacity for foreign payments. During 1953, the restrictions became more severe and affected not only total imports but the acquisition of capital goods.

Relatively speaking, the restrictions were relaxed in certain countries during 1954, owing to the hopeful prospects for the terms of trade and the capacity to import at the beginning of the year. Thereupon imports promptly increased by 9 per cent, thus exerting pressure on the balance of payments in the second half of the year, when unfavourable price changes set in.

The policy of controlling purchases on foreign markets was maintained in 1955, but apparently to a smaller degree than before. Colombia and Brazil, for example, where more liberal steps in relation to imports had been taken in 1954, applied restrictive measures in 1955, whose effects were felt almost at once in Brazil, and in Colombia during the latter part of the year. Conversely, Argentina, Chile and Mexico had adopted a restrictive policy in 1954, but permitted larger purchases to be made abroad in 1955. In the first two countries, this change of attitude was mainly attributable to the shortage of essential goods from which they had suffered in previous years; Argentina's heavier imports brought about a marked disequilibrium in the balance of payments. In the case of Mexico, the recovery in the capacity to import consequent upon a high volume of goods and services exported (including the tourist trade) was the element that permitted the expansion to take place.

In one way or another, trade policy in 1955 was invariably based on the principle of import replacement. (See table 7.) Yet the only significant change in the

Table 7. Latin America: Coefficients of import components in relation to available goods and services, consumption and investment, 1945-55

Average for	Capital goods as a percent- age of fixed investment	Consumer goods (as a percentage of consumption)	Raw materials	Fuels	Total imports as a percentage of available goods and services
1945-49.....	31.8	6.8	3.3	1.6	15.2

1955	31.0	4.5	4.5	1.9	14.0

Source: Official statistics.

composition of imports was the increase in the share of raw materials. In other words, the substantial imports effected in 1955 did not, as might have been hoped, promote a more rapid rate of capital formation which would have raised the investment coefficient. On the other hand, the improved supply of raw materials does seem to have encouraged a relative intensification of industrial activity in Argentina and in certain other countries which had been handicapped by shortages in previous years.

6. THE RELATIVE INADEQUACY OF SAVING AND THE INVESTMENT COEFFICIENT

The situation described above accounts only in part for the stagnation of the investment coefficient, which stood at about 16 per cent. Internal factors, which require analysis, were also responsible. Preponderant among these was the volume of saving. To judge by the coefficient of investment, that of saving, which began to fall in 1949, has apparently continued to slacken in recent years. (See again table 6.)

Since the need for a greater volume of savings, and Latin America's efforts in this direction, are well known, the factors determining the above phenomenon call for investigation.

The level of income in Latin America is low, as witness the fact that in 1955 annual per capita income in eleven countries was below 200 dollars (at 1950 prices), in seven it ranged from 200 to 450 dollars, and in two only did it exceed 450 dollars. Such income levels as these offer scant margin for any considerable acceleration of the rate of saving. As a general rule, even given the rate of saving prevalent in the Latin American countries, the consumption of a large proportion of the total population is very limited. Hence the moderate increments registered serve to raise consumption levels rather than to increase the capacity for saving. This situation was intensified by the population shifts that accompanied the economic development of the post-war years. The larger individual earnings of the population transferred from primary activities to the urban centres led to the adoption of higher standards of living and the creation of new needs, and were mainly absorbed by additional consumption. It must also be remembered that in Latin America the marginal propensity towards consumption is extremely great in the higher-income brackets.

The year 1955 was no exception to this trend. Aggregate consumption, in addition to rising more than 4 per cent above the preceding year's high level (which had already exceeded that of 1953 by 7 per cent), increased its share of total available goods and services and thus

caused a decline in the investment coefficient, despite the substantial growth of public investment. (See figure IV.)

Figure IV

LATIN AMERICA: CONSUMPTION AND INVESTMENT 1945-55

(As a percentage of available goods and services)
Natural scale

The foregoing conclusions not only account for the composition of imports, but also underline the vitally important fact that over the last few years private saving has grown in absolute terms only, as a result of the increase in income, while its relative position within aggregate goods and services has been gradually weakened. In 1955, private investment was barely maintained at the 1954 level. (See table 8.) Public investment, on the other hand, played a major part in determining total investment, as it registered the exceptional increment of 15 per cent.

Table 8. Latin America: Gross investment in fixed capital, 1945-55

Year	Gross investment		Gross investment	
	Public (billions of dollars at 1950 prices)	Private	Public (percentages of total)	Private
1945.....	1.0	2.7	27	73
1946.....	1.0	3.9	20	80
1947.....	1.1	5.0	18	82

1953.....	1.9	5.0	27	73
1954.....	2.0	5.4	27	73
1955.....	2.3	5.3	30	70

Sources: See appendix to this chapter.

A problem of fundamental importance for the future economic development of Latin America is thus raised. A relative stagnation of the investment coefficient does not prevent the gross product and gross income from maintaining an appreciable rate of growth, since this coefficient does not mean that investment fails to increase in absolute terms. On the other hand, it does indicate a certain weakness in Latin America's effort at capital formation, on which the region's hopes of accelerating its development must be based.

7. THE PRODUCT-CAPITAL RATIO

The share of the product-capital ratio in the trend towards recovery observed in 1955 still remains to be considered. Although the steadiness of foreign demand provided enough incentives to maintain over-all economic activity at a high level, the product per unit of capital remained the same in 1955 as in 1954. Even with the reservations proper to provisional estimates of the stock of capital, it would seem that the product-capital ratio, after declining since 1949, has tended to become stabilized in recent years. In 1955, there was no deviation from this trend. (See table 9.)

Table 9. Latin America: Product per unit of capital, 1945-55

(Billions of dollars at 1950 prices)

Year	Gross product	Stock of capital	Product-capital ratio
1945.....	29.8	64.4	0.46
1946.....	32.2	66.4	0.48
1947.....	34.0	70.0	0.49
1948.....	36.1	74.1	0.49
1949.....	37.2	79.0	0.47

1951.....	41.1	87.9	0.47
1952.....	42.2	92.6	0.46
1953.....	43.2	96.8	0.45
1954.....	45.9	101.7	0.45
1955.....	48.2	106.7	0.45

Sources: See appendix to this chapter.

The above statement can now be analysed in greater detail. Although statistics are inadequate, as they com-

prise only over-all data on public and private investment, they nevertheless shed some light on the problem.

It is well known that private investment is channelled towards agriculture or industry, for example, while public investment is primarily earmarked for basic projects, such as electric power stations, transport facilities, etc., which are of supreme importance, but whose productivity is only indirect and in any event slower to materialize. Such is the prevailing type of public investment, the marked increase in which weighed heavily in Latin America's total gross investment in 1955; it may therefore be inferred that the net capital added during the year had a product-capital ratio lower than that of the existing stock of capital, and that the latter had to be utilized more intensively for the average ratio to remain unchanged.

Statistics on investment by sectors of economic activity, which would have permitted a more accurate analysis of the problem, were not available. Without such figures the analysis of the evolution of the gross product by sectors proves unsatisfactory. (See table 10 and figure V.)

Table 10. Latin America: Rates of growth of gross product, by sectors, 1945-55

	1945-55	1954	1955
Agriculture	4.4	1.8	5.4
Mining	4.6	5.4	11.9
Manufacturing industries	6.1	7.1	5.8
Building	5.8	7.2	5.9
Other sectors	5.0	8.2	6.7
Gross product	5.1	6.3	5.9

Sources: See appendix to this chapter.

However, the product-capital ratio fluctuated in Latin America around a stationary level (0.45 per unit of capital) and the prospects of an upward movement seem to depend upon factors which operate slowly, save in exceptional years such as those during the Second World War.

II. TRENDS IN SELECTED COUNTRIES

1. ARGENTINA

(a) Recent development

The structural handicaps to which Argentina's economy has been subject during the last few years did not prevent per capita gross income from rising by 1.2 and 1.9 per cent in 1954 and 1955, respectively, in relation to its level in 1953. To assess the real magnitude of the increase, and its importance for the recent development of the country's economy, it must be noted that in absolute terms income during 1955—68 billion pesos (at 1950 prices) in round figures—was scarcely higher than in 1948 and 1951. If demographic growth is taken into account, per capita gross income actually stood at a level 10 per cent lower in 1955 than in the two years mentioned. The prolonged persistence of the stagnation that had in fact begun in 1948 shows that the circumstantial factors responsible for short-term fluctuations in gross income were accompanied by others likely to be prejudicial to Argentina's economic development over the long run.

Figure V
LATIN AMERICA: GROWTH OF THE GROSS
PRODUCT BY SECTORS

(1950 = 100)

Natural scale

This development was hampered by the precarious situation of two basic sectors of the economy: transport and energy. The shortcomings of the former were apparent from the condition of the railway system and of the road network, as well as from the availabilities of motor vehicles. The railways suffered an intensive process of disinvestment, estimated to have exceeded 20 per cent in little more than six years. Apart from the necessity of modernizing obsolete equipment, the failure to replace rolling stock has meant that only 25 per cent of the existing steam locomotives are in good condition, while 38 per cent are in urgent need of repair; the permanent way in use is from 32 to 50 years old and traffic density, measured on the basis of the distance covered annually by goods trucks, has declined in the course of a few years by 50 per cent. Again, the aggregate length of the road network, which in 1947 was 52,192 kilometres, had decreased to 51,582 kilometres by 1954. If it is further recalled that the highways have seldom been resurfaced and are for the most part in poor repair, the present condition of Argentina's road system can be readily understood. The lorry park is far from presenting a more hopeful picture. According to calculations, at least 100,000 units would have to be imported to renew it.

Electric energy is also undergoing a severe crisis, reflected in the shortage of electricity and the restrictions on consumption. In 1955, the capacity of the public-service power stations in Greater Buenos Aires was 800,000 kW; it is estimated that to meet existing demand some 300,000 more would be required, while this figure

would have to be substantially raised for the maintenance of a satisfactory rate of growth during the next few years. Not only has electric energy been in short supply, but the production of petroleum has been slow to expand, so that imports in recent years have absorbed an ever-increasing share of the country's scanty foreign exchange availabilities.

(b) Total demand

The rise in income during 1955 reflected the increment of 2 per cent achieved in the per capita gross product, thanks to 4 per cent and 7 per cent increases in the per capita product of the agricultural and industrial sectors, respectively. Most of the credit for the increment was due to industry, not only because its expansion was greater, but because of its preponderance within the total product. In 1955, Argentina's economy had the benefit of better weather conditions, a more satisfactory supply of raw materials and fuels and a rise in aggregate demand. The industrial recovery did not, however, mean that the per capita levels registered in previous years—1950 and 1951, for example—were exceeded.

Within total demand, the external sector continued to display the same symptoms of weakness as in recent years, and even exerted a stronger negative influence than in 1954. On the one hand, the volume of aggregate exports of goods and services contracted by 7 per cent; on the other, the terms of trade effect resulted in a loss 3 per cent heavier than had been suffered in the preceding year. In contrast, domestic demand expanded and determined a rise in total demand. (See table 11.)

Investment in fixed capital, which during the last few years had been limited mainly by inadequate availabilities of capital goods, increased by 7 per cent, or one billion pesos at 1950 prices, public and private investment contributing to this increment in similar proportions. While the external sector did not on this occasion, for the reasons outlined above, supply the incentives that induced the rise in investment, it did exert a favourable influence through the increase in imports of capital goods. On the other hand, some impetus may have been given by domestic consumer demand. But this latter stimulus was not absolutely essential, since the substantial investment requirements for basic sectors, industry, etc., remained unsatisfied. In Argentina's present economic situation, larger availabilities of capital goods would seem to be all that is necessary to promote investment. Per capita consumer expenditure rose by 2 per cent, or slightly more than the gross product.

The final outcome of these movements of investment and consumption was that total expenditure on goods and services increased by over 5 per cent in 1955, or, again, more than the gross product.

(c) Capacity to import

Broadly speaking, Latin America's capacity to import is inadequate. Within this over-all situation, Argentina constitutes a special case. It is perhaps the country where the capacity to import has undergone the most spectacular decline in recent years, owing to the exceptional factors analysed below.

If the movement of prices on the world market is taken into account, the capacity to import depended in

Table 11. Argentina: Gross product, terms of trade effect, consumption and investment, 1945-55

Sources: See appendix to this chapter.

the past, and still depends today, on exports of agricultural products. Since 1948, the volume of total exports has remained stationary, thus reflecting in reality the lack of incentives from which agricultural production has been suffering of late. The crop sector, in particular, has been in a state of stagnation for approximately ten years.

In the first place, this is the result of the exchange-rate and price policy applied to agricultural production and exports. An excessive external overvaluation of the peso caused an obvious disparity between its purchasing power on the home market and abroad. Under the official system of marketing exportable products, this meant that the domestic prices fixed for the producer were far from encouraging, especially when the successive increases in costs that affected Argentina's economy are borne in mind. Secondly, this latter circumstance deprived the producer of the resources he required to introduce improved technical methods, especially when agricultural activity felt the effects of an exodus of man-power caused by the attraction of the better wages obtainable in economic activities in the urban centres. The inflation from which Argentina's economy had been suffering for years, and which was attributable both to monetary factors and to over-all wage increases at a time when productivity was deteriorating, necessitated a redistribution of income

which had similar repercussions on the producers' capacity for capital formation.

All this exerted an unfavourable influence on agricultural production. The 21 million hectares which, on an average, were under cultivation during the period 1940-48, decreased in 1955 to 17 millions only. It must be recalled that within this total area, the contraction took place only in zones used for products whose prices were controlled, whereas production of those that could be marketed at free prices expanded by approximately 40 per cent. Furthermore, the reduction was to some extent offset by the enlargement of the area devoted to stock-breeding.

In 1955 the position of the capacity to import was more critical than in previous years, since it underwent a further contraction of about 13 per cent. This is explained by the evolution of exports and of prices on the world market, as already described. (See table 12.)

The slender capacity to import coincided with an increase of approximately 17 per cent in imports of goods and services, the result being a deficit in the balance of payments amounting to 1.6 billion pesos at 1950 prices. This disequilibrium meant that imports had exceeded the capacity to effect them by some 30 per cent. But it should

be noted that the heavier purchases abroad gave rise to an import coefficient (ratio to gross income) of only 9 per cent, which is one of the lowest figures recorded during the period 1945-55. Furthermore, this was practically the same as the coefficient registered in 1952, when a reduction of imports was caused by the deterioration of the capacity to import, due in its turn to the almost total loss of that year's crops. Thus, while the total volume of imports of goods and services expanded in 1955, it still failed to meet requirements of essential goods, although even so a marked disequilibrium in the balance of payments was recorded. This is the most patent manifestation of the weakness at present displayed by the external sector in Argentina.

(d) *Consumption, investment and the capacity to import*

The existing external disequilibrium is attributable not only to the adverse influence of the foreign sector, but also to the behaviour of factors which mainly operate within the internal economy. The whole economic process of the creation of income and its expenditure on consumption and investment brought about internal disequilibria which soon affected the balance of payments. The decline in the capacity to import and the balance-of-payments situation may also be analysed from this point of view.

It has already been shown that in 1955 the sum of consumption and investment was higher than the total volume of the gross product. For this to have been possible, imports must necessarily have exceeded total exports, and herein lay one of the determinants of the disequilibrium in the balance of payments.

This is no new state of affairs for Argentina's economy. On the contrary, virtually since 1948, and concurrently with a disequilibrium in the balance of payments, total expenditure and imports have exceeded the gross product and exports, respectively. It may now be asked which of the two components of total expenditure—consumption and investment—was responsible for the situation described, and what influence, both direct and indirect, they exerted on the capacity to import, which seems at the present time to be the focal point of Argentina's chief economic problems.

As from 1947, the coefficient of investment in fixed capital has been almost uninterruptedly declining, and since 1948 the same has been true of the absolute level of per capita investment, a trend which has thus coincided with the decrease in the gross product. On the other hand, per capita consumption rose by somewhat more than 6 per cent between 1947 and 1955. Hence it is clear that this growth was achieved at the cost not only of equilibrium in the balance of payments, but also of the absolute level of capital formation. This conclusion holds good for practically the whole of the period mentioned.

In addition, an expansion of consumption which was out of proportion to the possibilities offered by the evolution of income exerted a considerable influence on the internal economy and on the capacity to import. On the one hand, the growth of consumption was partly met through a reduction of the exportable balance, since it absorbed a greater volume of production. On the other hand, it seems to have combined with exchange policy

and the establishment of fixed agricultural prices to promote an internal redistribution of productive resources to the disadvantage of agriculture in general, and, specifically, of agricultural exports. Production for domestic consumption, in other words, was given stronger incentives not only by prices but also by demand. In short, this process implied that the increase in consumption, by curtailing exports, affected the capacity to import. If these repercussions of internal factors on the capacity to import are taken in conjunction with the effects of an unfavourable evolution of the terms of trade, it can easily be understood why imports in 1955, although inadequate to meet requirements, helped to determine the marked disequilibrium in the country's international accounts.

(e) *Exchange measures and the new agricultural prices²*

The new measures adopted in October 1955 for the exchange rate and agricultural prices were dictated by the need to remodel Argentina's economy and thus revive agricultural activity and the capacity to import. Attention has already been drawn to the adverse influence exerted on agricultural production by the fixing of low prices, and to the way in which these prices really depended on the pronounced overvaluation to which external peso quotations were subject. Hence the first measure to be put into effect was the devaluation of the Argentine currency (from 5.00 and 7.50 pesos to the dollar to 18 pesos), which more or less levelled down its external to its internal purchasing power. Simultaneously the various rates of exchange were standardized and the whole system simplified, despite the temporary multiplication of rates which may have resulted from retentions on exports—amounting to as much as 25 per cent in some cases—and from the surcharges and taxes on certain imports. A free market was also created for movements of capital and financial services, as well as for specific imports and exports. Subsequently, agricultural prices rose from 15 to 100 per cent, according to the product concerned. Further, retentions and exchange surcharges will serve to build up a National Economic Rehabilitation Fund, mainly designed to promote technical and economic improvements in agriculture and to pay subsidies whereby the possible effects of the devaluation of the peso can be mitigated.

The immediate outcome of devaluation and the new prices established for production has been a virtual redistribution of income in favour of the agricultural sector, especially as, at the date when these measures were adopted, the main crops had already been harvested, and no substantial increments in production will be registered over the short term. The object of this redistribution is to advance to the producer the resources he needs for increased capital formation.

Over the longer term, there are prospects of an expansion of Argentina's traditional crops. Here a decisive influence may be exerted by the stimulus of the new prices. Firstly, they tend to narrow the gap between the present relative profitability of the various crops and that recorded in previous periods, when harvests were large and exports heavy. Secondly, they may enable producers to use a larger volume of resources for mechanization.

²For fuller details, see the article entitled "The situation in Argentina and the new economic policy", in the *Economic Bulletin for Latin America*, Vol. I, No. 1 (January 1956), pp. 26 et seq.

zation and the introduction of better farming techniques, which will lead to an improvement in productivity. How far this is likely to happen, and to affect the expansion of production, depends upon two main conditions, namely, that there are no inflationary cost increases to absorb the profits accruing from the new prices, and that the rise in income is not solely used for a return to the farmer's previous levels of consumption.

In any event, if the expansion of production envisaged for the forthcoming agricultural season is to mean a higher capacity to import, the larger exportable balances which will be obtained must be successfully marketed abroad. There has been a contraction of Argentina's foreign markets for certain products, especially wheat, owing to a series of factors, which include the large stocks accumulated by the United States and Canada and the growth of European production. However, prospects are much more favourable for some items, such as maize, linseed, meat, dairy products, etc. An impartial weighing-up of the situation would seem to indicate that the world market could absorb a larger volume of exports from Argentina. In that case, the desired end of increasing the capacity to import would be achieved.

The next question concerns the role of these measures in relation to the industrial sector, which they must obviously affect both directly and indirectly. Firstly, if the capacity to import is successfully enlarged, improved supplies of raw materials and capital goods will facilitate the fuller utilization of existing capacity and, where necessary, the modernization of equipment. That is, it will be easier for the product-capital ratio to recover from the decline it has been suffering in the industrial sector. Furthermore, the exchange measures automatically afford greater protection to industry and better facilities for the exporting of some of its products. Presumably, too, higher agricultural earnings will result in a rise in demand for industrial products.

(f) *The price increase*

As a consequence of the devaluation of the peso and the incentives offered to the producer, there was, according to official estimates, a 10 per cent rise in prices. This increase differs radically from others previously experienced by the Argentine economy. These latter were the outcome of an inflation of costs promoted and stimulated by bank credit and by over-all wage increases unaccompanied by any expansion of productivity. In contrast, the price increment of 1955 is due to the modification of the exchange system, which raised the prices of imported goods. But to this increase resulting from devaluation others might be added, should they not be neutralized by an expansion of productivity. During the last quarter of 1955, the money supply grew much more slowly than in the same period of 1954, namely, at a rate of 2 per cent instead of 8 per cent. Although some of this increment in the means of payment was absorbed by the rise in prices due to devaluation, it still constitutes an expansionist factor which may influence prices if its effects are not absorbed by greater productivity.

On the other hand, the wage increases decreed in March 1956 may affect prices and incentives to the producer in a different way. Firstly, although these over-all increases would appear to amount only to 10 per cent, it must be recalled that the minimum wage has risen and

at the same time women's wages have been placed on the same level as those of men; hence they are estimated to be in many cases considerably larger. While wage increases are not absorbed by entrepreneurs' profits or by a proportionate expansion of productivity, they may bring about a further rise in costs and consequently weaken the incentives to agricultural production, on which, in the final instance, the restoration of the capacity to import depends.

2. BRAZIL

The upward trend followed by Brazil's economy during the last few years weakened in 1955, when the deterioration of the terms of trade and the decline in private investment and imports were among the most noteworthy changes that took place. As a result of exchange reform and restrictions on purchases abroad, the balance of payments approached equilibrium in the second half of the year, and closed with a surplus. But, apart from the reduction of imports already mentioned, another consequence was a rise in the prices of many raw materials and other imported production goods. Despite the control of bank credit, the inflationary forces of the economy—a fiscal deficit and heavy wage increases—maintained their latent pressure on the balance of payments.

Within the general setting characterizing the Brazilian economy in 1955, the per capita gross product grew by only a little more than one per cent, while per capita income remained practically stationary in marked contrast with its 8 per cent rise in the preceding year.

(a) *Trends in aggregate demand*

Aggregate demand was almost 2 per cent higher in 1955 than in 1954, whereas in this latter year it had expanded by 9 per cent. But it should be noted that the exceptional level attained by total demand in 1954 was attributable to a considerable improvement in the terms of trade and to an increase in consumption and particularly in investment. In 1955, in addition to the weakness displayed by total investment, substantial changes took place in the behaviour of the various components of aggregate demand. (See table 13.)

External demand, which had shown signs of depression in the first six months of the year, expanded considerably in the second half, and absorbed a volume of goods and services 10 per cent larger than in 1954. Nevertheless, the fall in average external sales prices neutralized the expansive effects of this increase in exports on the economy. During recent years, the considerable and more or less persistent improvement in Brazil's terms of trade has helped to promote a high level of economic activity, a rapid process of capital formation and a perceptible rise in per capita income. The favourable repercussions produced by the external sector had become the chief dynamic element in the Brazilian economy, by raising entrepreneurs' profits and total demand, and by enlarging the capacity to import; and, in reality, it was to the renewed impetus thus provided that the accelerated development of Brazil's economy had been adjusted. The ultimate outcome of the stagnation of the external sector in 1955 was the removal of incentives for internal demand.

If domestic demand was maintained in real terms at a level about 2 per cent higher than in 1954, this was principally due to the rise in consumption. Private consumption followed an upward trend, although less sharply than in earlier years. On this occasion it mainly reflected the influence of the over-all wage increases in the last six months of 1954 and the first quarter of 1955, which led to an expansion of consumer demand. However, as prices continued to rise, the effects of higher wages on such demand were gradually absorbed—especially in the second half of 1955—even though real wages still remained, on the average, higher than in 1954. The Government's current expenditure also exceeded that of the preceding year, and helped to determine the increment in total consumption. But deficit financing, combined with the wage increases mentioned, seems to have contributed to the continuance of the inflationary process which had already made itself manifest in Brazil.

In sharp contrast with the behaviour of consumption, aggregate investment decreased by 14 per cent, on account of the fall in private investment. In the first place, the deterioration of the terms of trade caused a contraction of the capacity to import which led purchases abroad to be reduced by more than 16 per cent. (See table 14.) At the same time, during the course of 1955 the higher

quotations for foreign exchange in the various import categories brought about a gradual rise in the prices of many imported raw materials and capital goods, which coincided with the inflationary increase in costs, as well as with a restriction of bank credit that was relaxed to some extent only in the second half of the year. In addition, the exchange policy in previous years has favoured over-investment in equipment, thus causing idle productive capacity in many industrial branches. Furthermore, the inflow of foreign capital, which had been exceptionally large in 1954, amounted in 1955 to less than 60 million dollars at 1950 prices. All this helped to discourage private investment.

In contrast, public investment increased considerably in 1955, but despite deficit financing—which did not imply a mere transfer of expenditure from the private to the public sector—the stimulus to private investment thus provided was insufficient to offset the depressive effects of the factors reviewed above.

(b) Production trends

The evolution of production, by sectors, followed the trends of aggregate demand, except in the case of agricultural products, where weather conditions intervened. Thus, agricultural production expanded by about 5 per

Source: Official statistics.

cent, mainly on account of the increment registered in certain products for domestic consumption, such as wheat, maize and rice, as well as in coffee and cotton. Cacao, on the other hand, was barely able to maintain the preceding year's levels. As against this trend, live-stock production showed a much smaller rise in inventories than in 1954.

For the gross product in the industrial sector, which reacted to the influence of the domestic demand situation already described, an increase of about 4 per cent contrasted with the 10 per cent increment recorded in 1954. The branch most seriously affected was that of production goods. The output of glass and ceramics declined by 3 per cent, and in the iron and steel making industry the volume of production was no larger than in 1954. It would seem that certain industries manufacturing capital goods also tended to remain stationary throughout the year 1955. Their level of activity reflected the restrictions on bank credit,³ the scarcity and high prices of certain raw materials and capital goods, the smaller inflow of foreign capital and the stagnation of aggregate demand, which affected private investment. The cement industry, on the other hand, while feeling the adverse effects of the decline in building activities, was able to offset them through the replacement of imports and, to a lesser degree, through the increase in public investment. Thus it achieved an expansion of 15 per cent, which was more intensive than that registered in 1954.

The industries producing consumer goods, taken as a whole, grew by 5 per cent. Not only was their output influenced by the rise in consumption previously indicated, but also restrictions on imports and the higher price of imported goods made themselves felt more strongly in the case of such commodities. This encouraged a more intensive utilization of productive capacity so as to compensate in some instances for the reduction in imports.

The remaining sectors of the economy seem to have kept pace with the growth of the population.

(c) *The balance of payments*

The balance of payments registered a surplus of about 2 billion cruzeiros. Nevertheless, as was stated at the outset, the pressures on this balance, which had brought about considerable disequilibrium in several years during the recent past, and especially in 1954, survived in latent form in 1955. If in that year they were not reflected in Brazil's foreign accounts, this was only because of the severe restrictions imposed on imports.

During the last few years the rate of growth of income has been more rapid than that of the capacity of import. The former followed a more or less uniform trend in the course of its intensive annual growth, whereas the latter was subject to somewhat marked fluctuations in the volume of exports and in the terms of trade. At all events, while income increased by more than 30 per cent between 1950 and 1955, the capacity to import did so only by approximately 18 per cent. This expansion of income, promoted by the behaviour of the external sector, was achieved through the intensive rate of capital formation, largely sustained by imports of capital goods. At the same time, this growth of income caused an increase

both in the demand for domestically-produced and imported consumer goods and in requirements of imported raw materials and fuels. Hence the propensity to import remained at high levels. In those years when this propensity was most fully satisfied, it was responsible for heavy deficits in the balance of payments, even at times when the capacity to import increased, as, for example, in 1951 and 1954.

It was to this type of pressure, originating in the rapid rate of development, that the balance of payments was subject. But, in addition, the inflationary repercussions of the internal economy had also affected the balance of payments in earlier years. In 1955, these influences continued to operate, although less intensively, to judge by the expansion of the money supply and the rise in prices. In any event, successive decreases in foreign quotations for the cruzeiro in the different import categories took place throughout 1955, thus reflecting the severe pressure on Brazil's balance of payments.

3. COLOMBIA

(a) *General trends*

The marked deterioration in the terms of trade which had already set in during the second half of 1954 sharpened during 1955, and thereby weakened one of the expansive forces that in previous years had promoted extensive and rapid economic growth. There was thus an interruption of the pronounced upward trend which had been characterized since 1945 by rates of growth that were high for the gross product and higher still for gross income and for available goods and services. Between 1945 and 1954, the average annual rate of increase of per capita gross income was 12 per cent. In 1955, income declined by 1.8 per cent, but the growth of available goods and services still kept pace with that of the population.

In contrast to the behaviour of the external sector, the dynamic forces of the internal economy and the compensatory policy pursued by the Government tended to maintain the level of economic activity, and mitigated the effects of the deterioration in the terms of trade by sustaining domestic demand and the investment coefficient. (See table 15.) The result, however, was a substantial disequilibrium in the balance of payments on current account. By 1955, this disequilibrium had become the dominant feature of the Colombian economy. Should present trends in the external sector persist, it would not be long before they affected the country's economic development.

(b) *Aggregate demand*

The favourable evolution experienced by the terms of trade in recent years reached its peak in 1954, with a 20 per cent improvement over the high 1950 level. In 1955, in contrast, an 11 per cent deterioration took place in relation to the previous year, mainly owing to the decline in coffee prices, which had already begun by the second half of 1954; simultaneously, the volume of total exports decreased by 3 per cent. Hence, the favourable terms of trade effect in relation to 1950 amounted only to the modest sum of 80 million Colombian pesos, as against 220 millions in 1954. (See table 16.) External demand, which had previously been mainly responsible

³ It is the production goods industries that resort most freely to bank credit in Brazil.

for the expansion of total demand, and therefore the most powerful of the dynamic forces affecting the internal economy, exerted a weaker influence, and would have had even greater depressive consequences than those described, but for the other dynamic factors mentioned, which can operate only over the short term.

The phase of Colombia's economic development whose outstanding features were the rapid growth of the gross product and of gross income, was followed by a far-reaching and radical change in the structure of the economy between 1945 and 1954. As regards employment by sectors, the relative share of employment in industry, energy, transport, commerce, etc., rose from 38 per cent in 1945 to 45 per cent in 1954, whereas the corresponding figure for agriculture fell from 62 to 55 per cent. A similar change in the stock of capital by sectors accompanied the channelling of investment towards more productive activities. As a result, the structure of production also underwent considerable modifications, since the export sector's share in the gross product dropped from 20 per cent in 1945 to 13 per cent in 1954. This process had two consequences of vital importance to Colombia's economy, namely, the partial displacement of the external dynamic element by the forces of the in-

ternal economy, and the related changes in the structure of aggregate demand.

Without the aid of the economic policy pursued by the Colombian Government in 1955, these changes might not have completely counteracted the negative operation of the external factors. The compensatory financing of the coffee purchases effected by the Federación Nacional de Cafeteros, the increase in public investment, and the exchange, monetary and fiscal policies adopted, all acted as neutralizing instruments and consequently helped to sustain total demand.⁴

Hence public and private consumer demand remained, in absolute terms, at a level similar to that of the preceding year, although the per capita figure was 2 per cent lower. Nevertheless, since exchange measures were aimed at restricting imports of consumer goods, the demand for domestic products was really higher than the year before. But even so, consumption of domestically-produced

⁴ For a detailed description of these measures, see "Colombia's economic policy in a year of balance-of-payments disequilibrium", in the *Economic Bulletin for Latin America*, *op. cit.*, pages 53-58. For other previous measures, see also "Impact of coffee exports on the economies of Brazil and Colombia" in the *Economic Review of Latin America* (special issue, Bogota, August 1955), pages 40-47.

goods was far lower than in earlier years, particularly 1954, when total consumption increased by about 10 per cent.

In demand arising from investment a 7 per cent increase was recorded, which, although below the 1954 figure, still enabled the investment coefficient to reach 24.6 per cent. Indeed, this was the chief factor tending to neutralize the effects of the terms of trade on aggregate demand. It should, however, be recalled that private investment increased by only 5 per cent, and mainly corresponded to the completion of projects begun at an earlier date and to the greater demand for production goods originating in the public sector. Public investment—extremely high in 1954—rose by more than 14 per cent in 1955; hence it was pre-eminently responsible for the maintenance of the above demand, which it affected both directly and by its subsequent expansive effects on the internal economy.

(c) *Production trends*

Agricultural production continued at the previous year's level. The coffee crop constituted a record for Colombia. Actually, price fluctuations have no short-term effect on this product, because of the special features characterizing its cultivation and the time-lag before any output is yielded. Moreover, in the second half of the year the surplus held by the Federación Nacional de Cafeteros was successfully sold abroad. For other crops, 1955 was at least as satisfactory as the preceding year, and in the case of some products for domestic consumption—rice, for instance—there was practically no need for imports.

The high annual rate of growth (12 per cent) registered for industry during the period 1950-53, was succeeded by very small increases in 1954 and 1955. In 1955 industrial output was chiefly maintained by virtue of the restrictions on imports of consumer goods and the demand for specific production goods deriving from the Government's heavy investments. But, clearly, the process of industrialization that had hitherto characterized Colombia's economic development was slowed down. In mining, which had suffered a crisis in 1954—particularly as regards precious metals—no change took place during the year. The other sectors also remained more or less stationary.

(d) *Deterioration in the terms of trade and external disequilibrium*

The deterioration in the terms of trade meant that they no longer represented either a dynamic force or—as in recent years—a factor permitting imports to increase without resultant balance-of-payments disequilibria. For a full understanding of the nature of this phenomenon, a salient feature of Colombia's economic development in recent years must be recalled, namely, the rapid and persistent expansion of imports, whose volume rose by 125 per cent within a decade.

Firstly, this development required ever greater quantities of capital goods for the economy to reach an investment coefficient which varied between 20 and 25 per cent of available goods and services during 1945-54. At least 40 per cent of these goods were purchased abroad. Secondly, the very rise in income, and population shifts

towards urban activities, modified the structure of demand. For instance, income-elasticity coefficients were very high for the principal durable and certain non-durable goods, and relatively high for processed food-stuffs. Most of these commodities also came from abroad, and offered a marked contrast with domestically-produced consumer goods, whose statistical coefficients were very low.⁵

While it is true that in recent years a process of replacing imports by domestic production has been taking place, this too has necessitated progressively heavier imports of raw materials. The magnitude of the increases in the groups of imports mentioned reduced the relative importance of consumer goods, as a result of the substitution process.

During this period—except in 1953—the increase in total imports was accompanied by a parallel growth of the capacity for external payments, brought about not so much by higher exports as by the favourable effects of the terms of trade. To grasp the full importance of these latter it should be recalled that between 1945 and 1954 they not only raised the capacity for external payments by 130 per cent, but also prevented the increase in imports, described, as well as the defrayment of heavy financial services, from causing any serious disequilibrium in the balance of payments on current account.

But, as has already been pointed out, the evolution of the internal economy in 1955 differed from that of the terms of trade. The deterioration in the latter, and a 15 per cent reduction in the capacity for foreign payments, coincided with a level of demand which continued to exert pressure on imports, and, at the same time, with heavier expenditure on financial services than in 1954. The various measures to restrict imports, mainly based on a system of multiple exchange rates, failed to prevent disequilibrium in the balance of payments on current account, the deficit amounting to some 200 million dollars (at 1950 prices).

(e) *Conclusions*

Many lessons of practical value for Colombia's economy can be learned from the experience of 1955. The internal dynamic forces have shown themselves capable, up to a point, of neutralizing, relatively and over the short term, the negative effects of a falling-off in external demand, and of maintaining the levels of the gross product, employment and effective demand. But it has also become apparent that their operation leads to strong pressure on the balance of payments and thence to disequilibrium, and that such pressure cannot easily be counteracted by means of restrictive measures like those adopted in 1955. Over the long run, the weakness of the external sector, should it persist, may seriously hamper economic development, through difficulties in the supply of capital goods and the consequent decline of the investment coefficient. Only the more energetic substitution of domestic production for imports of consumer goods and certain raw materials—which is far from easy to achieve at short notice—would allow Colombia to purchase more capital goods on foreign markets without considerably increasing its total imports, at least until such time as

⁵ See the article in the *Economic Bulletin for Latin America*, *op. cit.*, pages 55 and 58.

the country is in a position to produce many of the capital goods that must at present be acquired abroad.

4. MEXICO

The year 1955 witnessed an accentuation of the upward trend followed by Mexico's economy after the temporary contraction experienced two years before. Gross income rose by about 10 per cent and per capita income by approximately 7 per cent, thus exceeding for the first time the 1951 peak. However, Mexico's economy displays a series of features distinguishing the present boom from the phase of intensive development which culminated in 1951, while at the same time some of the disparities that marked the post-war period still survive. To describe both sets of characteristics as accurately as possible, and to interpret their meaning, the trends of aggregate demand, broken down into its various components, should first be analysed, and developments in the different sectors of production should then be examined.

(a) *Aggregate demand*

Among the components of aggregate demand, it was perhaps exports that, directly or indirectly, played the most active role. As regards their direct action, it may

be pointed out that the quantum exported was 23.2 per cent higher than in 1954. The indirect influence of this increase in exports was particularly apparent in private investment. The principal determinant of the growth of exports was the boom in the United States economy. In 1955, the satisfactory position with respect to external demand coincided with the completion of certain investment projects which increased both production and exportable surpluses, thus permitting an even greater expansion of exports.

Total gross investment rose by 16 per cent, but this upward movement was the result of divergent trends in public and private investment. (See table 17.) In fact, public investment—which in earlier years had exerted a decisive influence on the level of activity and the rate of development—contracted by nearly 10 per cent in real terms. In this sense 1955 was an exceptional year, since the only other recent case of a fall in public investment had occurred in 1953, when it caused an over-all decline in both demand and income, whereas in 1955 it was offset by the rise in private investment. This latter, in contrast to public investment, registered a proportional increase higher than that of any of the other components of global demand (40 per cent). Herein lay another of the peculiar features of the year under review, as until 1955 private investment in Mexico had been largely the direct outcome of activity in the public sector.

A major stimulus to private investment was provided by external demand, which maintained, and even rose above, its previous high level. Furthermore, the effect of two consecutive years of expanding agricultural production (the increment between 1953 and 1955 amounted to 30 per cent) was to enlarge the domestic market and improve investment prospects in the industrial sector. These incentives were strengthened in April 1954 by the devaluation of the currency, which not only encouraged exports, but also offered additional protection to industries producing for the domestic market. All this created a favourable atmosphere for private investment. Moreover, in several important sectors the Government took special steps to promote the expansion of private enterprise; among these should be mentioned, first and fore-

most, the official protection accorded to the creation of new industries manufacturing transport material, such as railway rolling-stock and motor vehicles.

Such inducements were accompanied by a parallel increase in the resources available for financing private investment. One of the factors that helped to determine the greater availability of financial resources was the widening of the entrepreneurs' margins of profit; this, in turn, was the result of devaluation and of the consequent inequality in price and wage increases. Another contributory cause was the intensification of the inflow of foreign capital, which reached an estimated net value of over 75 million dollars (including reinvestment), and financed about 15 per cent of private investment. (See tables 17 and 18.)

Source: Official statistics.

As a result of the interplay of these incentives and resources, private investment was channelled in three main directions: firstly, towards the expansion of productive capacity in the export sector, particularly as regards cotton, coffee and sulphur; secondly, towards those sectors of trade and industry that derived the greatest additional protection from devaluation, higher customs duties and the establishment of quantitative import restrictions, in which group the renewal of investment in projects shelved since 1953 should be incorporated; and, thirdly, as in Mexico's previous periods of prosperity, towards building for residential and commercial purposes. Otherwise, the process of investment in stockbreeding and in agricultural products for domestic consumption that had been initiated in previous years pursued its normal course.

Nevertheless, investment in production for the home market bore no relation to the growth of domestic consumption. In fact, consumer expenditure increased at a slower rate than the other components of total demand, with the obvious exception of public investment, which declined. Private consumption, which had expanded by 5 per cent in 1954, rose by 7 per cent in 1955, but adjustment of this figure to demographic growth demonstrates that real per capita consumption did not regain the peak level reached in 1951.

Although, within demand generated in the private sector of the economy, the growth of investment outstripped that of consumption, in the public sector the opposite was the case. While public investment, as has been shown, declined, the Federal Government's current expenditure increased by 10 per cent in real terms. This increment almost exactly offset the reduction in investment, since total public expenditure rose by 2 per cent.

(b) Production trends

A break-down of the various sectors' contributions to the expansion of production reveals the logical counterpart of the movements of demand just examined. Thus, in the agricultural sector—where an increment of nearly 10 per cent in relation to the preceding year was registered—the most substantial increases were recorded in export products (cotton, 18 per cent; coffee, 10 per cent; cacao, 10 per cent). Production for domestic consumption

expanded to a much lesser degree, or even decreased, in the case of maize, by 2 per cent, and in that of beans and wheat, by 5 per cent. Per capita availabilities of this last group of products remained almost unchanged, owing to the growth of the population and the sharp curtailment of imports.

Mining output, in response to the stimulus of external demand, increased by 15 per cent. The largest increment was registered for sulphur, but the production of zinc and silver also expanded considerably.

Production of electric energy and petroleum rose by about 12 and 7 per cent respectively. The influence of external incentives was also felt in the petroleum industry, since exports increased by 18 per cent, thus amounting to almost 29 per cent of total production.

Manufacturing output increased by about 10 per cent. But in this sector too there were great disparities between the different branches. Taken as a whole, the capital goods industries expanded their production by 20 per cent, whereas in those manufacturing consumer goods output rose by only 8 per cent. These differing trends are not surprising, given the movements of demand analysed above.

(c) Conclusions

External factors exerted a notable influence on the recovery of Mexican economy in 1955. Although these factors had already played a very active role on other occasions, as, for instance, during the Second World War and the Korean hostilities, there were two important differences between the situation then and in 1955. In the first place, neither of the two wartime periods created conditions that permitted an increase in imports of capital goods proportionate to the prevailing high levels of external demand. In the second place, the effects of public investment and external factors then tended towards the same ends, instead of operating in opposite directions as in 1955. Hence it would be difficult to match in recent times the active role played by external factors in determining the general level of activity and the channelling of resources.

Moreover, the 1955 boom accentuated some of the features of the economic evolution of the fifteen pre-

ceding years. The growth of consumption and wages was still slower than that of investment and profits. In this sense, despite the existing prosperity, there are still structural problems which may hamper the continuance of rapid and uniform development.⁶ The rise in agricultural income, the maintenance of a high level of external demand and the replacement of imports by domestic production, which acted as incentives in 1954-55, although

⁶ See the *Economic Survey of Latin America, 1953* (E/CN.12/358), United Nations publication, Sales No.: 1954.II.G.1, pages 98-99.

they brought about no major changes in these structural conditions, did counteract their adverse effects.

A trend still persists in internal demand which, closely following movements of income, has led to a rapid expansion of production goods industries, but has had an unfavourable effect on those manufacturing non-durable consumer goods, the insufficient market for which continues to retard development. Revived demand for domestic products in 1954 and 1955 has resulted, in other sectors, in a rise in prices rather than in increased production and consumption, owing to the inelasticity of supply and the heavier costs.

Appendix to Chapter I

CONCEPTS AND SOURCES

I. DEFINITION OF MAIN CONCEPTS¹

Gross product has been used for convenience throughout to mean the gross domestic product at market prices, that is, the market value of the product attributable to the factors of production located within the country before allowance for depreciation. It is equal to the sum of consumption expenditure, gross domestic capital formation and net exports of goods and services. It differs from the gross national product at market prices by the inclusion of net factor income payable to the rest of the world (i.e., investment income, such as interest, dividends and branch profits).

Available goods and services, entitled "total available means" in some countries, refers to the sum of consumption expenditure and gross domestic capital formation. Available goods and services plus net exports of goods and services (or less net imports) equals gross product as defined above.

Gross income has been used to designate the sum of gross national product in prices of a base year (1950) and the calculated gain (or loss) resulting from changes in the terms at which exports are exchanged against imports relative to the prices that prevailed in the base year. The adjustment for changes in the terms of trade is a measure of the change in the purchasing power of exports, which are here regarded as a means of obtaining imports from abroad. While gross national product and gross national income are identical aggregates when expressed in current prices, it should be noted that the two normally diverge when expressed in prices of a base year, except for the base year itself when the gain from changes in the terms of trade is of course nil.

Terms of trade effect is the title that has been applied to the gain or loss resulting from changes in the terms of trade relative to the base year (1950). It has been calculated as the product of exports of goods and services expressed in prices of the base year by the change, since the base year in the index of the terms of trade (the ratio of the unit value index of exports to that of imports); or, what amounts to the same thing, as the difference between the value of exports of goods and services deflated by the import price index and the same value deflated by the export price index.

Estimates in U.S. dollars of 1950 are obtained by means of conversion rates established by ECLA for 1950. These rates are intended to approximate the over-all purchasing power parities between the currencies of the various countries of Latin America and the United States dollar of 1950 purchasing power; they are admittedly very approximate. A systematic study is now under

way aimed at providing more precise and satisfactory conversion rates for use in future studies.

Chapter II

FOREIGN TRADE AND THE BALANCE OF PAYMENTS

I. INTRODUCTION

An increase in the volume of exports and a reduction in their unit value were the outstanding factors which influenced Latin America's foreign trade during 1955. Both operated with equal intensity, so that any advantages which might have been expected from the greater efforts to produce export commodities were neutralized by the fall of prices.

But the data for 1955 still compare favourably with those for 1950. Despite a reduction of 6 per cent in relation to 1954, the price index was 8 per cent higher than in 1950 and the quantum of exports reached an all-time peak of 7,230 million dollars;¹ this figure was 6 per cent above the 1954 level, 11 per cent larger than that of 1950 and 4 per cent greater than the previous maximum recorded in 1953. Imports continued to rise and their volume increased by 2 per cent. Here again, statistics for 1955 were higher than for any former year, including even 1951. In relation to 1950, the advance in imports amounted to 27 per cent, so that the index substantially exceeded that of exports. The price of imports rose slightly because of the heavier freight charges.² As a consequence, the terms of trade deteriorated by 7 per cent in relation to the previous year and by 1 per cent when compared with those of 1950.

The pronounced change of trend which occurred in the course of the year should also be noted. During the first six months of 1955, exports showed no signs of increasing; on the contrary, the decline which had begun in the second half of 1954 became sharper and imports—although lower than in the previous six months—remained at a high level. In marked contrast, the current value of exports during the second half of 1955 exceeded 4 billion dollars, a figure which had never previously been reached even during the most active period of the Korean War. Furthermore, foreign markets remained more stable and higher prices were quoted for the main commodities exported by Latin America, with the exception of cacao and wool. The improvement in the region's trade balance during the second half-year mainly arose from the peak exports of coffee from Brazil and Colombia, of chilled meat from Argentina and of wool from Argentina and Uruguay. Similarly, the measures to reduce imports adopted by a number of countries at the beginning of 1955 had a greater effect in the latter part of the year.

Statistics emphasize the significance of the change. While Latin America's favourable trade balance during the first six months fell to only 115 million dollars, during

the second half-year it stood at 320 millions. But annual balances have shown a serious decrease, from 1,241 million dollars in 1953 to 657 in 1954, and to 435 millions in 1955.

Latin America's balance of payments was slightly more unfavourable than in 1954. The reduction in the trade balance, which could not entirely be offset by the small rise in the net inflow of capital, was the direct cause of this deterioration.

Needless to say, these factors have all affected the individual countries of Latin America in a different way and to a different degree. But it should be noted that the contrasts became more pronounced during 1955. Figure VI shows how far the countries diverge from one another as regards increases or decreases in the current value of their exports.

Figure VI
LATIN AMERICA: PERCENTAGE CHANGE IN
THE CURRENT VALUE OF EXPORTS
BETWEEN 1954 AND 1955

The dissimilarities in this respect have been more marked, as a result of variations in the volume of exports and in the prices of the commodities which exert the strongest influence in each case. But there were also considerable discrepancies in the import sector. Table 19 identifies the factors which affected the foreign trade of each individual country in the region during 1955. Although a general analysis of these trends follows later, some examples of outstanding situations should be noted: Mexico and Venezuela raised their imports far less than their exports; Argentina and Bolivia, conversely, imported much more while their exports declined; and Brazil obtained a small surplus in its balance of payments, thanks to a 20 per cent reduction in its imports.

¹ At 1950 prices.

² This increase has resulted in a surcharge of some 15 per cent on the transport costs of the region's imports, which represents an approximate increment of 1 per cent in c.i.f. prices.

Source: National statistics; some of the 1955 statistics are estimates.

^a The countries have been divided into four groups as follows: I. Those with a favourable balance of payments, and (a) an increase in the current value of their exports, or (b) a decline in the current value of their exports; II. Those with an unfavourable balance of payments, and (a) an increase in the current value of their exports, or (b) a decline in the current value of their exports.

The disequilibria, extremely serious in some cases, which have appeared or have become more acute in several countries since the final months of 1954, were reflected in the trade and exchange policies of the countries concerned. Such disequilibria are fundamentally due to the unequal growth of imports and exports. (See figure VII.)

The situation prevailing at the beginning of 1955 led the countries with a balance-of-payments deficit to reinforce restrictions on imports, following the normal procedure for such controls. Simultaneously, and with greater vigour than before, Governments renewed their efforts to encourage domestic production, in order both to raise the export quantum and to further the process of import replacement. Measures were also adopted to impart greater flexibility to the outflow of export commodities, their trend being towards a reduction in the administrative controls applied and in the overvaluation of exchange rates. This new policy—especially as regards Argentina—is too recent to allow its results to be assessed.³ But it is already evident that such measures

have acted as a major stimulus to wool exports from Argentina and Uruguay. Nevertheless, the attempts of the Latin American countries to increase their resources by means of greater exports, in the case of most products, encounter serious obstacles deriving from the instability of prices and demand on markets outside the region.

II. THE BALANCE OF PAYMENTS

The year 1955 witnessed substantial fluctuations in the balance-of-payments situation of the Latin American countries in relation to 1954; in most countries they arose from the marked changes in the capacity to import and, in some cases, from modified import policy. (See table 20.) The variations in the value of exports largely determined the changes in the capacity to import.

A considerable deficit replaced the surplus of the preceding year in Argentina, Bolivia, the Dominican Republic, Ecuador and Honduras, while the previous deficit increased substantially in Colombia and Uruguay. In

³ It would likewise be premature to analyse the new policy pursued in connexion with trade treaties and payments agreements. The multilateral agreement between Brazil and the "Hague Club" took effect only in the final months of 1955, while the international aspects of the change in Argentina's trade policy have not gone

beyond the stage of preliminary contacts. This change presents problems which require detailed study, the most significant, perhaps, being the maintenance, within a multilateral system, of the reciprocal credits included in bilateral agreements, which have proved very useful in recent years and in 1955 as well.

Figure VII

contrast, Chile, Cuba, Guatemala and Mexico, which had suffered a deficit in 1954, reacted favourably in 1955. The same occurred, although to a lesser extent in Paraguay. Brazil was able to correct the serious disequilibrium which had characterized the evolution of its balance of payments during 1951-54; Venezuela showed a considerable increment in its balance-of-payments surplus. Only Costa Rica, El Salvador and Peru experienced no major changes, in relation to 1954, in the positive or negative balance of their foreign accounts, which continued to be insignificant in size.

A glance at statistics for the whole region shows that the favourable and unfavourable balances largely offset one another and, although liabilities were finally greater than assets, the deficit was small in relation to the sum total of the external transactions which were carried out during the year. The existence of similar circumstances in 1954 deprives such over-all data of much of their significance.⁴

⁴ But the implications of such data had been of great importance in 1953, because a considerable and almost universal decrease in imports had resulted in large surpluses in most of the countries, which had a cumulative effect for the region as a whole.

1. TRENDS IN THE CURRENT ACCOUNT OF THE BALANCE OF PAYMENTS

(a) Trade

The aggregate value of Latin America's exports in 1955 remained at a level similar to that of 1954. This was a consequence of the differing evolution of the volume and the average price of exports, the former having been 6 per cent higher and the latter 6 per cent lower than in 1954. Since the aggregate value of imports in 1955 was more than 200 million dollars greater than in the preceding year, the favourable trade balance, which had been over 650 millions in 1954, fell to some 430 millions in 1955. (See again table 20.)

It should be pointed out that no fewer than six countries—Venezuela, Mexico, Chile, Cuba, Nicaragua and Paraguay—all had surpluses arising from greater exports (including revenue from the tourist trade in the cases of Mexico and Cuba). Brazil also recorded a favourable trade balance, but it resulted from a reduction in imports. Two countries, Peru and Panama, had deficits despite increased exports. In the case of Peru, this development was attributed to the substantial inflow of capital which

^a For the grouping of the countries, see table 19.

led to purchases abroad whose value exceeded that of exports. The other countries in general showed unfavourable trade balances, mainly caused by the reduction in their exports, which was substantial in Argentina, Colombia and Uruguay. (See again table 19.) It should be noted that Argentina, which until a few years ago ranked as the largest exporter in the region, has held only third place since 1952. The further decline in its exports during 1955 emphasized this situation even more.

The aggregate trade balance of those countries that showed a surplus stood at 1,266 million dollars, of which 1,130 millions were contributed by the countries which had attained this position through an expansion of their exports. The unfavourable balance of the remainder—577 million dollars—was accounted for mainly by the countries whose exports decreased during 1955.

The geographic distribution of trade underwent some modifications. Exports of Latin American products to the United States witnessed a minor improvement after two slack years which largely arose from the larger volume of exports of petroleum and iron ore, to the slight rise in sugar exports and to the higher prices for copper. But it should be noted that a greater share of both sugar and copper exports were shipped to European markets. Heavier exports to Western Europe in 1955 sustained the trend visible since the early post-war years; they were almost 5 per cent higher than in 1954 (see table 21). In contrast, exports to Japan dropped by 21 per cent. Although complete data are not available on which to

base an analysis of inter-Latin-American trade or of that maintained with the countries of Eastern Europe, it seems clear that the former declined during 1955, whereas the latter reached a somewhat higher level, mainly because of sugar exported by Cuba and Mexico to the Soviet Union and the increase in Argentine imports from that area.

As regards the origin of Latin America's imports, a new decrease took place in acquisitions from the United States, Canada and Japan, while shipments from Western Europe increased. Nevertheless, the reduction in purchases from the United States during 1955 was entirely caused by the situation in Brazil. While Brazilian imports from this source dropped by the large sum of 200 million

dollars, the other countries of the region raised their aggregate purchases from the United States by 100 millions. Mexico, Venezuela, Chile and Argentina, in that order, were among the countries where such imports increased most rapidly in 1955.

(b) *The rise in cargo rates*

One of the determinants of the increase noted in the value of Latin America's imports was the higher rate charged for the transport of cargoes. (See table 22.) Between July 1954 and the end of 1955, the various

categories of maritime freight tariffs rose in very different proportions, although the increment was substantial in most cases. World indices published to date increased for cargo boats without a fixed itinerary from 85.4 to 141.6 and from 67.6 to 154.1 (1947 = 100), depending upon whether the contract was for a single journey or for a specific period of time; in the index for tankers the increment was even more spectacular, from 56 in July 1954 to 248 in December 1955, after violent fluctuations in the interim. The annual averages for 1954 and 1955 rose by 40 and 70 per cent in the case of tramp ships and by more than 55 per cent for

^b Non-financial services mainly include expenditure and revenue on account of patents and registered trade-marks, of various government transactions and of tourist trade.

^c Increased revenue for the Republic of Panama from the Canal offsets the greater expenditure of the other countries.

tankers.⁵ Other sources—especially the official West German index and that of the United Kingdom Chamber of Shipping—show increments of the same size. The latter, for example, recorded increases ranging from 45 to 53 per cent between 1954 and 1955 in the averages for the transport of coal, cereals and sugar in cargo boats without a fixed itinerary. The cost of carriage of general cargo by shipping on regular routes rose to a much smaller degree, as was natural, since the rates on such lines are always more stable than those of other types of shipping. The West German official index—which covers regular shipping under any flag and may thus be considered representative of the world trend—shows an increment of 12.5 per cent between July 1954 and December 1955. But to judge from other information,⁶ it appears that up to the end of 1955 regular United States shipping lines were charging almost the same rates as those in force a year previously.⁷

The reason for the higher maritime transport rates lies in the expansion of world trade during the past 18 months. The index of the quantum of world exports rose from 101 to 110 between the third quarters of 1954 and 1955 (1953 = 100); in other words, it advanced much more

rapidly than the increment in the available cargo space.⁸ The volume of trade with Western Europe increased far more than that with other regions and was also characterized by a disproportionate growth of bulk cargo and of the transport of liquid fuels.⁹

The effects of the rise in freight costs upon the unit price of Latin America's imports appear to have been weaker than those revealed by the world trend. This is partly because a relatively large share (more than one-fourth) of these imports is composed of general cargo earned by regular shipping lines and partly because the freight charges of ships under the United States flag rose less, an important consideration, since the United States provides almost half of aggregate Latin American imports. An additional influence may have been the fact that the total volume of the region's imports increased very little. Furthermore, approximately one-seventh of all Latin America's trade is carried overland.

These factors, whether favourable or unfavourable, affected the various individual countries in differing degrees. Mexico, whose sea-borne trade is limited and

⁸ The net annual increase in world shipping is estimated at about 3 per cent.

⁹ The volume of crude petroleum transported by tankers has increased by 50 per cent during the last three years. The amount of coal carried doubled between 1938 and 1953. There were also increments, although proportionately smaller, in the volume of the trade in cereals and sugar.

⁵ See *Norwegian Shipping News*, January 1956.

⁶ See *Export Trade and Shipper*, New York.

⁷ As from January 1956, the West Coast of South America Northbound Conference raised transport rates for South American copper by 20 per cent.

in addition is mainly carried on with the United States, hardly suffered at all from the higher transport costs. Nor did the countries of Central America and the Caribbean feel their effects to any great extent, as these republics trade mainly with the United States and import a high proportion of general cargo. The consequences were somewhat more noticeable for the Pacific Coast countries of South America, although, except in the case of Chile, their imports of liquid fuels are small. In contrast, the combined effects of high volumes of bulk cargo, liquid cargo and trade with Europe were felt in those countries whose imports are brought by the South Atlantic route. But these latter have also derived higher revenue from their own merchant shipping.

In view of these considerations, as well as the composition of the volume of Latin America's imports,¹⁰ the surcharge originating from the higher cargo rates in 1955 may be estimated to have varied between 12 and 15 per cent for the region as a whole.

(c) *Other items in the current account*

As in previous years, transactions arising from tourist activities were mainly concentrated in Mexico.¹¹ In 1955, the inflow of United States tourists, which had increased after the peso devaluation of 1954, became still greater, and thus reinforced the favourable influence of higher exports on Mexico's capacity to import. Tourist receipts also rose in the Caribbean countries. On the other hand, to judge from incomplete data, tourist expenditure on the part of Brazil, Chile and Mexico declined somewhat, perhaps because of the sharp rise in the free market rates of exchange. Expenditure of Mexican tourists abroad also decreased.

Official grants from Governments outside the region—particularly those from the United States under its external aid programmes—were of little significance in relation to the aggregate income of Latin America; but in some countries they played an important part. In the case of Bolivia, for example, such grants from the United States were higher than in 1954 and caused the capacity to import to rise by 21 million dollars, that is, by 22 per cent. Similarly, Guatemala and Haiti received grants-in-aid which contributed to a definite improvement in their exchange situation.

The very high proportion of the remittances of profits and interest channelled to the United States is a traditional feature of the region's balance of payments. Most of these transfers were made by Venezuela, Brazil, Mexico, Chile and Peru, countries where foreign investment is substantial. (See again table 22.) Except as regards Brazil, the remittances made by these countries rose in 1955, but this increment was not so great as to modify the favourable trend in the current accounts concerned. In point of fact, it mainly resulted from the intensified activity of the export sector, principally due in its turn

to the foreign investments made in previous years.¹² The decline in Brazil's transfers may be attributed to the reinvestment of a large share of the profits within the country, which was doubtless a consequence of the higher exchange rates applied to financial remittances transferred abroad.

2. TRENDS IN THE CAPITAL ACCOUNT AND NEW FOREIGN INVESTMENT

After two years in which the favourable balance in the capital account had decreased substantially, there was an appreciable increment in net income during 1955. The considerable increase in private investment, which had fallen in 1953-54, was the major determinant of this upswing of income, and offset the drop in long-term official loans. (See figure VIII.)

Figure VIII

LATIN AMERICA: AGGREGATE AND ITEMIZED BALANCES IN THE MOVEMENT OF CAPITAL

The short-term capital account as a whole underwent certain favourable modifications; if the situation changed for the worse in some countries, it showed a notable improvement elsewhere. Incomplete data show that the outflow increased in several Central American countries, Bolivia, Chile and, particularly, in Uruguay, while it

¹⁰ Studies of Latin American imports in 1952 gave the following break-down of a total of 31 million tons: 15.5 million tons of liquid fuels; 8.7 million of general cargo and 6.8 million of bulk cargo.

¹¹ In 1954 it was already calculated that Mexico received 20 per cent of the total expenditure—exceeding 1 billion dollars—of United States tourists travelling abroad.

¹² Despite the insignificance of the figures involved, the increase in remittances by Argentina, especially to the United Kingdom, should be noted. At the end of March 1955 an agreement was signed providing for the transfer of interest and profits for a sum of 1.5 million pounds sterling up to the end of June 1956.

was reduced in Cuba and Mexico. In the latter country, capital began to be repatriated as a result of the favourable evolution of the economy after the devaluation in 1954.

The decline in the inflow of official long-term capital during 1955 contrasted with the previous increase and was partly due to smaller disbursements on loans authorized by the Export-Import Bank. (See table 23.)

This is all the more striking because the amount of the development loans authorized in 1954 had increased considerably.¹³ On the other hand, the new loans authorized by the Export-Import Bank were also smaller in 1955, even though a credit of 60 million dollars was granted to Argentina for the installation of an iron and steel plant.¹⁴ The International Bank for Reconstruction and Development transferred slightly more capital to Latin America than in 1954, while new loans decreased in size. Outstanding among the latter were credits granted to Peru and Colombia for 26 million and 20 million dollars, respectively.

The economic activities which benefited most from loans granted by these two banks were still transport and agriculture. But there was an increase in the loans for industry and the production of energy, while those for mining decreased. Thus, in 1955 greater importance was attached as a rule to activities directly concerned with meeting basic national needs than to the export sectors. The disbursements made by the two banks mainly favoured Brazil, Colombia, Mexico, Peru and several Central American countries.¹⁵

Nevertheless, as repayment of another series of development loans granted in the post-war period by both banks has now begun, the weight of amortization borne by Latin America as a whole continued to rise and in several countries exceeded the lower receipts, in strong contrast with the considerable positive balance recorded in 1952-54.

¹³ For example, no disbursement has been made from the 100-million-dollar loan granted to Peru, which represents about two-thirds of the regional total authorized in 1954.

¹⁴ Nevertheless, it should be noted that the Export-Import Bank has declared its intention to expand its operations in the future; the decision to sell its portfolio bonds to private investors confirms this statement. Again, new loans and disbursements for stabilization increased during 1955.

¹⁵ In the investment field, the proposed creation of an International Finance Corporation has opened up prospects whose full scope cannot yet be assessed. In 1955, the United States acceded to the new Institution and laws were passed in Costa Rica, Ecuador and Haiti authorizing the Governments to become members.

No data are available for a table giving detailed statistics on new private investment of foreign origin during 1955. To judge from incomplete information, heavier private investment by the United States after 1954, and the probable maintenance of a higher level of investment by other countries, were the two main factors in the improvement which took place during 1955 in the long-term private capital account.¹⁶

But, to grasp the full significance of the increase in 1955, it should be noted first and foremost that the inflow of private capital from abroad during 1954 was of limited importance in relation to such receipts in 1951 and 1952. (See again figure VIII.) Moreover, the remittances of profits on foreign investment reached some 750 million dollars in 1955 and continued to be far in excess in the inflow of private long-term capital.¹⁷

As in 1954, a large proportion of the new capital entering Latin America was channelled towards industry and trade. Despite the appreciable volume of investment in the petroleum sector, the amount of capital received by mining as a whole could not be compared with the substantial sums invested during 1950-53. A brief examination of the situation in a few countries will illustrate the foregoing statements more clearly and will show the geographic distribution of the long-term capital inflow.

¹⁶ To these factors may be added the lower Latin American purchases of bonds in the United States, in so far as this decline did not represent a reduction in the short-term investment of the reserves of central banks. Information is not available on the share contributed by such investments over the short and the long term. In 1954, the total had increased substantially and it seems that most of the increment arose from short-term purchases by the Banco Central de Cuba. As regards efforts to expand future investment in Latin America, mention should be made of the Inter-American Conference, held at New Orleans, and attended only by private businessmen and companies. During this conference it was decided to create a private investment trust which will sell its shares in the United States and invest the capital received in new private enterprises in Latin America. The target fixed for the successive sales of shares is a total of 100 million dollars.

¹⁷ For methodological reasons, the discussion of these remittances appears in the analysis of the current account. (See above p. 26, for the significance of the increase in such remittances.)

During the post-war period, the largest share of aggregate foreign investment in the region was placed in Venezuela, and almost entirely in petroleum production. The inflow of capital for this purpose declined later when profits were reinvested, but the development of iron-ore mining implied new and substantial capital receipts in dollars. In 1954-55, investment in iron ore came to an end, but other sectors began to attract foreign capital, particularly industries to produce rubber, tyres and petro-chemical products. Furthermore, although it has not yet led to an inflow of capital, a contract has been signed between the Venezuelan Government and two Italian companies for the investment of 173 million dollars in an iron and steel plant.

Investment in the petroleum industries of Colombia and Peru continued to decline, probably because the results obtained from drilling and prospection were not very promising. But in Peru the decrease was offset by increments derived from new sums invested in trade, as well as in heavy and light industry. Similarly, in Chile and Mexico, the industrial sector—particularly the chemical and manufacturing industries—received more capital from abroad than in 1954. To judge by the investments already authorized, the legislation on foreign investment adopted by Chile in 1954 appears to have had a very favourable reception in Western Europe and the United States.¹⁸

On the basis of the few data available, it may perhaps be stated that the inflow of capital rose somewhat in Brazil.¹⁹ About half of these new investments were placed in the manufacturing sector.

It is well known that in 1953 Argentina established a new statute relating to foreign investment, whose volume had been small in the immediate post-war period. At the close of 1955, investments authorized under this altered régime amounted to some 40 million dollars, much of which appears to have already taken the form of machinery and equipment brought in especially for the mechanical industry. A trend towards greater activity on the part of foreign investors was thus apparent; but the supply of such capital to date is very far from meeting balance-of-payments and economic development requirements. It is hoped that the devaluation of the Argentine peso, decreed in October 1955, will not only encourage exports but will also provide a stimulus for foreign investment. Furthermore, imports of capital goods without the use of foreign exchange were once again authorized in some cases.

3. THE BALANCE-OF-PAYMENTS SITUATION AND FINANCING METHODS

The net balance-of-payments situation of Latin America as a whole was unfavourable in 1955, the deficit amounting to some 100 million dollars. This negative balance primarily reflects the behaviour of the balance of

payments in Argentina, Bolivia, Colombia and Uruguay, although other countries contributed to the result in a much smaller degree. It was the evolution of exports that exerted the greatest influence both in most of the countries with a deficit and in those where a surplus was recorded in the balance of payments. (See again table 20.)

An examination of the nine countries which had a favourable balance in 1955 shows that in six of them—Venezuela, Mexico, Chile, Cuba, Nicaragua and Paraguay—the surplus reached 338 million dollars and was mainly determined by the increase in exports. On the other hand, of the eleven countries where an unfavourable balance existed, nine—Argentina, Colombia, Uruguay, Ecuador, Bolivia, El Salvador, Haiti, the Dominican Republic and Honduras—had a deficit principally resulting from the contraction of their sales abroad. The total negative balance of these nine countries amounted to 467 million dollars.

But the revenue derived from non-financial services and the inflow of capital—although it generally had only a limited effect on the final result of the balance of payments—did serve in some cases to improve the favourable position caused by the trade balance and in others to offset the imbalance arising from trade.

Among the countries with a favourable balance, Venezuela is outstanding for the size of the surplus. A new peak in petroleum sales chiefly accounted for the substantial increment in the favourable balance in relation to 1954. The notable improvement in Mexico was largely due to greater exports—especially of cotton—and to higher receipts from the tourist trade, although an increase in long-term investment and a smaller outflow of short-term capital both made a contribution. The pronounced improvement in Mexico's balance-of-payments situation represented a vigorous reaction to the problems which had arisen during the first half of 1954.

The favourable balance in Cuba was attributable to similar causes, although they operated less intensively. The situation in 1955 also contrasted with the deficit in the previous year. Chile too found itself in a better position, thanks to the combined action of an increase in the volume of its exports and an improvement in the terms of trade. Higher exports were also the main element determining the surplus in Nicaragua's balance of payments.

Conversely, Brazil, Costa Rica and Guatemala, which showed a favourable balance in their foreign accounts, witnessed a decline in their exports. Guatemala's small positive balance arose from an increase in official grants. In Brazil the surplus was the consequence of a large reduction in imports aimed at the adjustment of expenditure to a lower level of income. Furthermore, the sum of the external commitments contracted during previous years, in order to relieve exchange difficulties, apparently exerted pressure in Brazil and made it necessary to stabilize the balance of payments during 1955.

Argentina should be mentioned first among the countries which showed a deficit, because of the considerable size of the unfavourable balance. The decline in exports of cereals led to a substantial decrease in the capacity to import which, combined with some expansion of imports, caused a deficit of some 200 million dollars as compared with a surplus of 100 million in 1954. In

¹⁸ The new legislation for the copper-mining industry, adopted in early 1955, also appears to have been well received. Some of the producing companies have announced a considerable expansion of their investments for 1956.

¹⁹ Aggregate foreign investment rose by 45 per cent, but this was mainly due to the increased reinvestment of profits. In turn, the higher reinvestment arose more from the decision to reduce the transfer of profits than from a definite policy to raise investment.

Uruguay, also, despite the contraction of imports, reduced exports and lower prices—especially for wool—united to weaken the balance-of-payments situation. The drop in export values, caused by lower coffee prices, and some delay in adapting expenditure to the subsequent reduction in the capacity to import, determined a deficit of more than 100 million dollars for Colombia; the previous surplus in Ecuador also became a deficit. But increased imports in Peru were offset by a substantial

inflow of capital and the negative balance was thus small. The continued deficit in Bolivia was caused by greater purchases abroad during 1955. (See again table 21.)

As in previous years, the methods of financing balance-of-payments deficits differed in the countries which fall within the dollar area and in those outside it. (See table 24.) But it is interesting to note that the United

^a The share of errors and omissions corresponding to clearing accounts has been included.

^b For the account of gold and exchange reserves, the sign (—)

represents an increase in the reserves; in fact, for book-keeping purposes, the account does in fact receive an asset. The sign (+) represents an outflow.

^c The figures for 1955 are partly estimated.

States granted new consolidation loans to Brazil for a longer term (up to eight years), and these loans are to be used to liquidate short-term commitments. On the other hand, some countries—especially Argentina, Chile and Colombia—bought surplus agricultural products from the United States Government; they were thus able to save convertible exchange, since such purchases were made in national currency. Lastly, the trend towards an increase of medium-term credits should be noted; they are called “deferred payments” and are granted by various European countries to finance imports of equipment.²⁰ Bolivia was one of the main beneficiaries under this system and was able to cover its deficit through the use of such credits.

Argentina and Uruguay—which are outside the dollar area and normally transact most of their foreign business with inconvertible currency areas—financed a high proportion of their deficit by means of credits included in their bilateral payments agreements. (See again table 22.) But Colombia and Ecuador were obliged to resort freely to their holdings of gold and convertible currency to cover the deficit in their foreign accounts. Although Haiti, Honduras and the Dominican Republic used such reserves to a far smaller extent, in absolute terms, they also had to use a larger relative share of their aggregate holdings.

²⁰ Under this system, some of the national currency derived from the sale of the surpluses is loaned to the recipient country for purposes of economic development and can be reimbursed in dollars over a period of up to thirty years. Consequently, these transactions may be regarded, up to a point, as development loans. The same is true of the consolidation loans, in view of the period allowed for their amortization, and of the “deferred payments”, since they can be used to import capital goods.

Elsewhere, of the countries which showed a surplus of some size, Venezuela, Mexico and Cuba increased their gold and dollar reserves. The same was true to a lesser degree of Guatemala. Chile, which is not in the dollar area, liquidated a proportion of its outstanding trade debts and of the deficit which had accumulated in the accounts of its bilateral agreements.

Brazil recorded both an increase in reserves and a substantial reduction in the short-term commitments contracted in former years, which had reached a high level. Nevertheless, the surplus in Brazil was caused by a sharp curtailment of imports; in fact, the favourable situation of the short-term commitments mainly arose from the consolidation loans mentioned above, which were granted by private banks and official institutions in the United States.

III. TRADE AND EXCHANGE POLICY IN LATIN AMERICA

One of the most striking features of the year 1955 was the lack of correlation between export and import trends in a number of Latin American countries. Argentina and Bolivia made considerably more purchases abroad, despite the decline in their exports; the same was true, although to a lesser degree, of Costa Rica, the Dominican Republic, El Salvador, Guatemala and Honduras. The position was reversed in Nicaragua and Paraguay, where the expansion of exports and the contraction of imports enabled these two countries to restore equilibrium in their balance of payments. Outstanding examples of disparity in the evolution of exports and imports are also

provided by Colombia and Brazil. In Colombia, imports remained at almost the same level, although exports decreased by 11 per cent; whereas in Brazil a much greater reduction was recorded in imports than in sales abroad.

All these situations, apparently differing widely from one another or even in complete contrast, reflect the existence of one and the same basic problem. The pressure of domestic demand—not only to satisfy direct consumer demand for imported goods, but even more to supply industry—tends to grow more rapidly than the resources derived from exports. In some years this pressure induces the country to effect more imports than are justified by the volume of such resources, and measures then have to be adopted to stabilize the balance of payments.

If 1950 is taken as the base year,²¹ the volume of imports can be seen to have increased 27 per cent by 1955, while exports expanded by only 11 per cent and the terms of trade became slightly unfavourable. These figures give a clear idea of the gravity of the problems affecting the Latin American countries, especially if it is remembered that the share of imports in the formation of the gross national product amounts to approximately 16 per cent, and that many republics have been compelled to cut down their imports of non-essential consumer goods. On the other hand, it is similarly obvious that the extension and diversification of the external credit facilities at the disposal of the countries of the region have somewhat eased the pressure of demand, although the fact that mainly short-term credits are involved may affect the availability of future income.

Broadly speaking, it can be noted that official anxiety to restore and encourage exports has been gradually increasing during the last few years. This largely accounts for the trend towards a progressive normalization of exchange régimes, designed to put an end to the external overvaluation of currencies. In the long run, this overvaluation has proved to exert a depressive influence on exports.

Without going into further detail, an attempt will now be made to indicate the characteristic features of some recent developments, and to examine the means adopted to remedy the situations in question.

1. BRAZIL

The value of Brazil's exports was very heavily reduced in 1955, partly because of the fall in coffee prices. This was not the main factor involved, as there was a notable recovery in the volume of exports, after the sharp decline which took place in 1954. Even so, receipts from coffee were 97 million dollars less in 1955 than in 1954. Income from cotton also decreased by 103 million dollars, in consequence both of a much smaller volume of sales and of somewhat lower prices. Furthermore, the capacity to import was affected, to an even greater degree, by the delayed action of previous disequilibria; in 1955, 210 million dollars were paid out on account of short-term trade debts accumulated over recent years. Some favour-

able factors partially mitigated the consequences of these adverse circumstances. Although the evolution of external markets resulted in a 255-million-dollar reduction in the value of exports of the three staple products, coffee, cotton and cacao, which produced only 1.052 billion dollars in 1955, the greater efforts made by domestic producers successfully raised the proceeds of exports of less important products (outstanding among which was pinewood) from 255 to 320 millions dollars, that is, by 25 per cent. Nevertheless, Brazil was compelled to enforce severe rationing of the foreign exchange at the disposal of importers. The contraction in imports amounted to 324 million dollars, expressed in current values, and to 12 per cent in terms of volume. The result was a favourable trade balance of 116 million dollars, thanks to which the current account of the balance of payments was stabilized.

So great a curtailment of imports was achieved by means of an exchange régime which enables the amount of foreign currency granted to importers—among whom it is distributed by a system of bidding—to be strictly established beforehand. In consequence of this policy, the country's debtor position was eased, the sum of its outstanding trade payments commitments was reduced and the rapid liquidation of those arising from recent purchases was ensured. On the other hand, the system of auctioning the scant supply of foreign exchange available for imports intensified the pressure exerted by the demand for foreign goods. Owing to the competition among importers, the agios paid over and above the old official rate rose rapidly and uninterruptedly, from an average of 22 cruzeiros to the dollar during the first few months of the new exchange régime (at the close of 1953), to over 80 in December 1955.

As regards the effect of the contraction in imports on their composition, preliminary indications, based on data for nine months, show a marked reduction in purchases of raw materials other than foodstuffs. Nevertheless, the indices of industrial activity continued to rise during the same period. Although the inadequacy of available statistics does not allow the importance of this factor to be assessed, there can be no doubt that the development of Brazil's own industry in recent years has led to the production of a number of items to replace imports, especially in the categories of spare parts for machinery, tools, chemical and pharmaceutical products, electrical appliances and processed materials. Not only have imports of this kind been replaced, but such commodities are also beginning to be exported, at least to neighbouring countries and to Chile.²² All this is in conformity with the natural trend of Brazil's economic growth. However, the selective encouragement of investment in new branches of industrial production—a policy which has been pursued for several years now—has clearly helped to stimulate import replacement and to promote new lines of production for export. The development of mining in the Rio Doce valley has enabled exports of iron ore to be increased by 40 per cent, the foreign exchange proceeds approaching 30 million dollars.

²¹ The year 1950 was relatively favourable for Latin America from the balance-of-payments standpoint, since it closed with a net surplus of 274 million dollars.

²² Recent information confirms that alarm clocks were exported to Argentina, lorries and sewing-machines to Bolivia and various types of tools and machine tools to Chile. Data are also available on sales of electric adding-machines to Venezuela and Mexico. In the aggregate, the value of export permits for manufactured products rose from 5 million dollars in 1954 to 18 millions in 1955.

Among the measures adopted by the Brazilian authorities in 1955 with a view to maintaining or expanding exports, modifications of the exchange rates must also be mentioned. There was no question of putting a premium on exports, but rather of progressively adjusting the rates concerned to the level simultaneously determined by the inflationary rise in domestic costs and by the fluctuations of sales prices on foreign markets. Brazil's staple exports did actually benefit in 1955 from these adjustments. One of the most noteworthy was introduced in January, and took the form of the classification of export products in four categories with exchange bonuses—from 17.19 to 31.70 cruzeiros to the dollar—over and above the basic rate of 18.36 cruzeiros. Coffee, for which a special lower rate had originally been maintained, was included in the second category from February onward, a step which represented an increment of 10 cruzeiros to the dollar. Subsequently, half-way through the year, cotton, cacao, pinewood and tobacco were also transferred to a different category, the corresponding rate of exchange rising by 6 cruzeiros to the dollar. Most secondary products were then likewise accorded a more favourable exchange treatment. The remarkable recovery of exports in the second half of the year and the reopening of markets formerly lost must be attributed to these measures.²³

Again, the entry into production of new petroleum refineries resulted in a saving of foreign exchange which is calculated at 17 million dollars yearly. Owing to the increase in consumption, however, effective expenditure continued to rise. Clearly this increment would have been greater had the development of domestic refineries not intervened. The figures for the first eleven months of 1955, compared with those for the same period in 1954, show that imports of petrol and fuel oils fell from 6.2 million to 4 million tons, while imports of crude petroleum expanded from 60,000 to 3.2 million tons. The volume of total imports, taken in the aggregate, grew by 16 per cent, and their value by only 3 per cent (5 million dollars).

2. COLOMBIA

The evolution of Colombia's foreign trade diverged considerably from that of Brazil in 1955. Both countries suffered the effect of the fall in coffee prices, but the situation in Colombia differed from that of Brazil inasmuch as the increase in the volume exported was negligible. Neither was any expansion registered for other products, so that the volume of Colombia's total exports declined slightly (by 0.9 per cent).²⁴ The index of their unit value, according to Colombian statistics, decreased by 10 per cent.²⁵

²³ A case in point is that of carnauba wax, which regained its footing in the United States market, whence it had been ousted by candelilla wax from Mexico.

²⁴ The data given here are not identical with the figures published in "Colombia's economic policy in a year of balance-of-payments disequilibrium", *Economic Bulletin for Latin America*, Vol. I, No. 1 (January 1956), p. 53, some of which were provisional.

²⁵ This figure is somewhat surprising, when it is recalled that coffee constitutes about 83 per cent of total exports and that its mean export price was reduced by 20 per cent, or, on an average, from 80 to 64 cents per pound. In point of fact, the 10 per cent reduction relates only to the registered values of exports. The loss suffered by Colombia's economy was at least half as great again, owing to the narrowing of the margin of foreign exchange placed freely at the disposal of exporters.

Owing to a slight rise in average import prices, the terms of trade deteriorated in 1955 by over 11 per cent in relation to 1954. Imports, however, remained at almost the same high level which they had reached in the latter year, the consequence being a trade deficit of 87 million dollars at current values. Again, foreign exchange reserves declined by 118 million dollars, that is, by 44 per cent, despite the fact that the amount of trade payments in arrears which remained outstanding was estimated at about 100 million dollars.

The various measures adopted in the course of 1955 to stabilize the balance of payments have been fully discussed in a recent document.²⁶ Such measures operated indirectly through a considerable increase in the exchange surcharge. The situation in Brazil was reversed in Colombia, where exchange surcharges were established beforehand without direct restriction of the amount of foreign exchange to be utilized. It would seem that this indirect method proved slower and less effective in its operation, since the total value of Colombia's imports was virtually the same in 1955 as in the preceding year (672 million dollars in 1954 and 671 in 1955). It should be recalled here that the figure for 1954 represented a substantial increase—122 million dollars or 22 per cent—in relation to 1953. Nevertheless, an examination of monthly statistics clearly shows that the boom in imports which characterized the last few months of 1954 had already been halted in the first six months of 1955. Between July and December the contraction became much more definite. From 366 million dollars during the latter half of 1954, imports fell to 350 millions in the first six months of 1955 and to 321 in the second half of the year. Meanwhile, new measures adopted in October and November—more energetic, although still indirect—originated a sharpening of the downward trend, which became manifest in the early months of 1956, when the value of imports classified in the preferential and primary categories declined by a further 40 per cent. If this rate were maintained, the decrease in the outflow of foreign exchange would easily exceed the annual reduction of 160 million dollars, which was the target set up by the authorities.

As regards the composition of imports, the effects of the measures adopted early in 1955 deserve some comment. If data for that year are compared with those for 1954, it will be seen that imports of consumer goods, fuels and raw materials contracted in a proportion ranging from 6 to 15 per cent, while imports of capital goods expanded by almost 10 per cent, until they represented more than half total imports. This fact radically modifies first impressions of the efficacy of the measures for curtailing imports, which actually took effect more rapidly than seemed to be the case, but only upon those items where they could logically do so, that is, upon imports of products for which long-term sales contracts are not required. It seems inevitable that an import structure in which the share of capital goods is almost 50 per cent should be unable to react quickly to abrupt changes in economic activity or to restrictive measures. Another point worth noting is that the reduction in imports of raw materials created no difficulties, at least up to the end of 1955. Moreover, all the raw materials essential for the normal functioning of industrial activities were

²⁶ See the article mentioned in footnote 24.

included in the preferential and primary categories, thus enjoying priority and a favourable exchange rate.

Colombia's economic policy was also directed towards the development and enlargement of foreign markets. Not only was the benefit of the free exchange rate granted to products of secondary importance,²⁷ but, in addition, the restriction imposed in May on imports from countries with which Colombia had a trade deficit led to a slight increase in exports of coffee to Europe, although at some sacrifice of price levels which was reflected in a surcharge on the value of the products imported.

With respect to production for import substitution, emphasis should be laid on the domestic iron and steel making industry, which succeeded in meeting about 50 per cent of consumption requirements. Similar stress must be laid on the great expansion of cotton production, thanks to which the Colombian textile industry is now self-sufficient as far as ordinary fibre is concerned. Tariff duties on imports of cotton and its by-products were therefore increased as from last November.

3. ECUADOR

Ecuador was the country in which income from coffee and cacao suffered the greatest proportional reduction in 1955. To the fall in prices were added the effects of a poor cacao crop. Fortunately, 50 per cent of the 20-million-dollar decline in receipts from these sources was offset by a noteworthy rise in exports of bananas, rice, and Panama straw hats. Despite the difficulties encountered in the marketing of rice, shipments abroad doubled during 1955, but this did not prevent the stocks accumulated since 1953 from increasing as well, on account of the unusually good harvest. As for exports of bananas, they continued to follow an upward trend, and Ecuador became the foremost world supplier.²⁸ If it is admitted that the rise in coffee and cacao prices in 1954 was exceptional, Ecuador's production for export can be considered to have maintained the trend towards rapid development which had begun in 1950 and which had allowed larger imports of capital goods to be effected and economic development to be promoted.²⁹ The curtailment of imports in 1955 affected capital goods less than the other categories, so that their quota increased in relation to the preceding year from 37.1 to 39.6 per cent of total imports. From 15 million dollars in 1950, imports of capital goods rose to 40 million dollars' worth in 1955; this permitted the rapid development of the textile industry, among other activities.

The means employed to restrict imports were of varying kinds. Indirect action was taken, in that application for import permits had to be accompanied by an advance deposit of their value; but direct measures were also adopted, in the form of an extension of the list of prohibited imports. Imports were thus reduced by an amount

rather larger than that of the decrease in exports, but even so equilibrium was not achieved either in the trade balance, where the deficit remained almost the same as in the preceding year, or in the balance of payments, which was further affected by other factors. Tighter restrictive measures will probably have to be introduced, as, owing to the unfavourable evolution of the trade and financial situation in 1955, three of the limits which monetary legislation defines as critical for Ecuador were overstepped. In fact, the country's foreign exchange reserves were reduced in one year by more than 25 per cent, and dropped to less than 30 per cent of the annual value of imports and below 40 per cent of the money supply.³⁰

Ecuador's exchange system authorizes multiple rates within a margin narrow enough not to distort the relation between domestic and world market prices. Exports of marginal products may be stimulated by the granting of total or partial participation in the benefits of the free rate of exchange, but the difference between the official rate of 15 sucres to the dollar and the free rate has not exceeded 15 to 20 per cent in recent years, except on very rare occasions. It has thus been sufficiently flexible to enable production for export to find markets abroad. The only exception has been rice, for which the Government grants direct subsidies and arranges agreements with foreign countries, for instance, Canada, because of the high production costs of this commodity.

Furthermore, new measures have recently been adopted with the aim of promoting exports and production for import replacement. An Instituto del Café and a Comisión Nacional del Trigo have been set up. Studies on banana pests have also been encouraged. Previous efforts have already yielded some results, among them the increase in exports of washed coffee, for which prices have improved. The noteworthy increment in the production of bananas was partly due to the implementation of the official road transport programme.

4. ARGENTINA

In Argentina, the poor maize harvest was the principal cause of the 9 per cent decline in the value of exports. This decrease would have been considerably greater if a recovery in wool sales during the last few months had not taken place. The satisfactory trend shown by the wool market after the exchange reform introduced in October 1955 has been maintained during the early months of 1956, thanks to the large purchases made by Japan and the United States.³¹ The boom in exports of chilled meat which had already begun in June as a result of the return to free trading in meat in the United Kingdom was also intensified at the time of the exchange reform. The progress achieved was so remarkable that Argentina ousted Australian meat from second place on the British market. Nevertheless, Argentina's trade bal-

²⁷ In contrast with the official rate of 2.50 Colombian pesos to the dollar, the free exchange rate stood at more than 4 pesos to the dollar at the close of 1955.

²⁸ The smaller output in Honduras and Guatemala made a circumstantial contribution to the rise in the demand for bananas from Ecuador.

²⁹ With 1950 as the base year, the volume of Ecuador's exports rose from 69 in 1949 to 100 in 1952 and 118 in 1955, slight recessions being recorded in 1951 and 1953.

³⁰ Reserves in gold and foreign currency fell from 34.1 to 23.4 million dollars during the course of 1955. In March 1956, the Junta Monetaria prohibited imports of spirits, tinned goods, passenger cars and 50 other non-essential articles.

³¹ For a more thorough analysis of the measures for the encouragement of exports decreed in October 1955 by the Argentine authorities, see the article entitled "The situation in Argentina and the new economic policy", *Economic Bulletin for Latin America*, pp. 26 et seq.

ance suffered a severe disequilibrium in 1955, largely owing to the expansion of imports. The contraction effected in previous years had meant that raw materials and spare parts for industrial equipment were in such short supply that a relatively considerable increase in import permits became essential.

The terms of trade were highly unfavourable to Argentina, despite a slight improvement in export prices. Their deterioration was due to a marked increase, amounting to 9 per cent, in the unit value of imports, the explanation of which no doubt partly lay in the rise in sea freight charges, which principally affected transport between Europe and the South Atlantic seaboard.

5. URUGUAY

Uruguay also felt the effects of such increments in ocean transport costs, but with the aggravation of a considerable decline in the unit value of its exports. The factor of most importance, however, was the almost entire disappearance of exportable balances of meat. The value of total exports fell by 27 per cent, even though sales of wool greatly increased towards the close of the year. As in the case of Argentina, these sales have continued during the early part of 1956, especially those to the United Kingdom, the Netherlands and the Soviet Union. The application of a more favourable exchange rate also exerted some influence, but as this was only a temporary concession the year's exportable balance was completely liquidated in a few months.

In contrast to Argentina, Uruguay reduced its imports in 1955, thanks to the direct action of the control mechanism which limited the granting of permits. Nevertheless, the decrease in imports was not so great as the decline in exports, and the trade deficit already apparent in the preceding year was thus aggravated. Again, the imports formerly effected had provided industry with its normal supplies, so that the restrictive measures most strongly affected raw materials, since the share of capital goods increased. A relative increment was also to be seen in imports of consumer goods. This was apparently a consequence of the special features of the exchange system, which is conducive to exaggeratedly large imports of non-essential and even luxury goods, as it is these that can most easily carry the price surcharges necessary to offset the direct or indirect subsidies required by many export products on account of their high costs.

6. CHILE

An increase of 17.7 per cent in current export values gives the measure of the improvement in Chile. The larger volume of exports and better sales prices were responsible for this figure. Again, the more moderate rise in average import prices finally resulted in an improvement of almost 8 per cent in the terms of trade. Even so, the volume of imports had to be strictly controlled, as the reductions effected in previous years, combined with the highly inflationary state of the internal economy, had intensified the demand for all categories of goods from abroad to such a point that it was far from being satisfied by a 7 per cent increase in the volume of such purchases. Particularly striking is the marked percentage decrease in raw materials, which

lowered stocks and at times created problems for the transforming industries.

Again, difficulties encountered in previous years had left the country saddled with a large backlog of payments at the beginning of 1955. The positive balance registered in the preceding financial year substantially eased this burden of arrears—dating from 1953—and strengthened the country's foreign exchange reserves. The fact that the favourable developments which took place in 1955 have persisted during the early months of 1956 gives grounds for the hope that outstanding external commitments will be liquidated at an early date.³² Meanwhile, it has been deemed necessary to maintain—at least in its essential aspects—the control of imports by means of lists of authorized products.

Nevertheless, the improvement of Chile's position in 1955 and the possibilities arising from a prospective increase in copper production capacity—thanks to new and substantial investments already resolved upon by the foreign companies—do not mean that the drawbacks of the Chilean economy's excessive dependence on the world market position for a single product can be disregarded. Receipts from copper accounted for 66 per cent of the value of all exports in 1955, an even larger proportion, that is, than in recent years. Moreover, exports of other products have declined, with the consequent aggravation of the trend apparent since 1953 both for animal and vegetable products and for manufactured goods. In this latter group the downward movement is even sharper if semi-processed copper goods are excluded from the total. Among mineral products, a fresh recession in nitrates is apparent. On the other hand, a noteworthy increase in sulphur exports was made possible by barter arrangements, but involved a heavy surcharge on the price of the commodities imported by this procedure. The falling-off in many secondary exports noted during the last few years does not reflect a decline in the country's production capacity; it is largely the consequence of an over-complex exchange system which lacks the flexibility called for by the rise in production costs that monetary inflation has brought in its train. It is hoped that the co-ordinated measures now being adopted to promote a normal exchange situation and financial stability will restore the indispensable equilibrium between domestic costs and external prices, and will thus enable production for export to be remodelled on sound and rational bases.

7. PERU

In 1955, Peru's imports and exports alike exceeded all previous figures. However, imports, which increased from 250 to 300 million dollars, showed a much more striking expansion than exports, the value of which rose from 238 to 260 millions. It is true that the growth of these latter has been steadier, imports having been lower in 1954 than in 1953. And it should also be emphasized that only two years ago, when imports rose to 293 million dollars—that is, 7 millions less than in 1955—there was a trade deficit of 71 millions which led to a 25 per cent devaluation of the national currency. On the other hand,

³² The official foreign exchange budget for 1956 allocates a sum of 92 million dollars to the payment of arrears. It seems that this amount comprises not only trade debts properly so-called, but likewise transfers corresponding to imports effected in 1955 and normally payable in 1956.

a slightly larger volume of imports in 1955 resulted in only a small reduction of less than 3 million dollars in the country's international reserves.³³ This favourable evolution was largely due to a 22 per cent increase in exports, and shows how much stronger Peru's economy has grown and how far the country has enlarged its capacity to import. This of course does not mean that a trade deficit of almost 30 million dollars gives no grounds for anxiety.³⁴ The operation of the high propensity to import within a free trade and exchange régime calls for strict vigilance in the manipulation of those indirect devices by whose action the equilibrium of the balance of payments can be protected.

In the case of Peru, the 20 per cent increase in imports registered for 1955 relates directly to the expansion of the internal private sector, and is jointly attributable to the growth of the gross product, a very marked expansion of credit³⁵ and a distribution of income which, by favouring the higher income levels, led to a disproportionate rise in the demand for imported products. Both the increment in imports and the somewhat inflationary character of internal expansion may also have been influenced by the remarkable development of the transforming industries. In this connexion, symptoms of a significant change in Peru's economic evolution can be observed. Although there is no waning of interest in the development of the basic sectors of the economy—energy, communications, rehabilitation of land—or in the expansion of production for export, both domestic and foreign manufacturing enterprises have increased in number and dimensions. Several factories are being installed with a view to replacing imports of essential products, and others of some years' standing, after meeting national requirements, are now competing on world markets.³⁶

Naturally, such exports of manufactured goods are effected only on a small scale as yet, and expansion continues to depend on the development of mining and the staple industrial crops. A 47 per cent increase in the volume of its exports within five years places Peru almost on a level with Venezuela, with one of the highest indices in Latin America.

These features of Peru's economic development explain why a trade balance deficit equivalent to 10 per cent of the value of imports caused no serious balance-of-payments disequilibria.

In the course of 1955, Peru obtained three development loans from the International Bank for Reconstruction

³³ This reduction in the reserves is not without importance, however, in view of their low level (they barely amount to the equivalent of one month's imports). Consequently, despite the stability of the currency, the stand-by credit of 30 million dollars contracted in 1954 has had to be extended for another year.

³⁴ After the value of exports of bullion has been added to that of exported goods.

³⁵ Loans from private commercial banks increased by 20 per cent in 1955 and deposits by 15 per cent—that is, in unprecedented proportions.

³⁶ Among the items which are being produced to replace imports, mention should be made of matches, explosives for mining, tyres and inner tubes, paint, refractory products for industrial purposes, fertilizers and cement. Exports of footwear in 1955 to Ecuador, Bolivia and Central America were valued at one million Peruvian soles. It is a striking fact that this industry, which grew up under the shelter of strong tariff protection, is now proving itself capable of competing in price and quality on the open market. This seems to be a result of the keen competition among the various national enterprises.

and Development, totalling 25 million dollars. Furthermore, a French bank granted a 27-million-dollar credit to the Corporación del Santa. A private United States bank accorded another credit for the sum of 9 million dollars to the Government of Peru for agricultural development in the Ica valley. Only a small proportion of these loans was used in 1955 to pay for imports of capital goods. The balance, which is in the nature of 50 million dollars, will swell the capacity to import over the two coming years. Besides these development credits, an increment estimated at 9 million dollars in short-term private commercial credits also helped to finance the excess of imports over exports, as did the purchase of wheat and butter from the United States accumulated surpluses, to a value of 7 million dollars, payable over the long term and in Peruvian national currency.

8. MEXICO

Despite a slight deterioration in the terms of trade as compared with the preceding year, the evolution of Mexico's foreign trade was very favourable in 1955. After decreasing over a period of three years, imports once again expanded, reaching a value of 884 million dollars, or 12.3 per cent more than in 1954. Exports, however, followed an even more dynamic course, rising from 657 to 790 million dollars, that is, by 21.1 per cent. This accounts for the reduction of about 50 million dollars in the trade balance deficit, which is traditionally offset by income from the tourist trade, also higher in 1955. Mexico's success in reversing the long-term trend towards a greater increase in imports than in exports was largely due to measures of economic policy and the continued demand for Mexican products abroad. Another distinguishing feature of Mexico's foreign trade during the year under review was the still heavier curtailment of purchases of consumer goods, while the share of total imports represented by capital goods and raw materials continued to expand. Here again State policy enacted an important role.

The exceptional increment in the volume of exports was mainly due to cotton, and, in a lesser degree, to coffee, copper, petroleum and zinc. Cotton sales rose from 260,000 to 350,000 tons, their value representing about 30 per cent of total exports. This increase in volume—as in the case of coffee, where it amounted to 84,000 tons, or 21 per cent—was principally attributable to an expansion of production, partly brought about by the official development measures. Nevertheless, it should be noted that if exports increased, they did so in spite of the none too favourable position of these two products on the world market. There can be no doubt that a significant part was played by the 1954 devaluation, which enabled Mexican prices to compete with falling world quotations. Liquid fuels ousted lead from third place among Mexico's exports. It is therefore not surprising that metals accounted for a smaller proportion of exports, although the volume of zinc sold abroad rose by 10 per cent. A reduction was also to be noted in the case of sisal, but this was partly because Mexico adopted the policy of processing it and selling it in the shape of manufactured products, instead of exporting the fibre.

The increase in the current value of imports was due on the one hand to the 7.3 per cent enlargement of their

volume, and on the other to the rise of 4.6 per cent in the price indices. The composition of imports evolved along lines of considerable interest from the economic standpoint. While the volume of imports of consumer goods decreased from 26 per cent of aggregate imports in 1954 to 19 per cent in 1955, the share of capital goods and raw materials rose from 45 to 49 and from 21 to 24 per cent, respectively.

These modifications were closely linked to a policy of import replacement and selective control. Purchases of foodstuffs had steadily increased since 1953, as domestic production, despite its growth, did not suffice to meet the country's heavier requirements. This induced the Mexican authorities to adopt active agricultural development measures. As a result of this policy and weather conditions,

in 1954 and to a still greater extent in 1955, the production of foodstuffs expanded considerably; self-sufficiency was virtually achieved in certain products which were formerly imported in large quantities, notably wheat, maize and beans. Moreover, the development of production allowed imports of lubricants to be cut down, and, while this did not imply that the share of fuels in the total value of imports was reduced, it offset the heavier purchases of crude for the northern zone of the country, to which transport of the domestic product is difficult. Finally, within the policy of selective control of imports, the restrictions and higher customs tariffs applied to imports of consumer goods—especially passenger cars—as well as the granting of tariff concessions to capital goods were invariably dictated by the need to encourage economic development.

Chapter III

AGRICULTURE

I. GENERAL ASPECTS AND PROBLEMS

1. PRODUCTION TRENDS

Agricultural activities in Latin American followed two divergent trends in 1954/55. Conditions favourable to the sector producing for the domestic market—which accounts for most of the agricultural output—were accompanied by others that hampered the normal development of production for export. As internal demand for foodstuffs and raw materials expanded with the growth of the population, as income rose and urbanization proceeded apace, a situation propitious to agriculture was created and Governments infused new energy into development policies aimed at self-sufficiency. On the other hand, such factors as the downward movement of world prices and the accumulation of staple export surpluses—both inside and outside the region—militated against the successful marketing of such crops. Nevertheless, thanks to the measures adopted by a number of Governments—such as minimum prices and more advantageous exchange rates—the Latin American farmer did not bear the whole brunt of the decline in the world market for

agricultural commodities. Moreover, the fall in prices took place after crops were sown, so that, apart from sugar, production was not affected.

After a period of hesitant growth following the Second World War, Latin America's agricultural production recovered somewhat in 1954/55, the rate of growth slightly exceeding the average for the previous ten years. As a result of good weather in the main agricultural areas, the volume of production reached a new peak, rather more than 5 per cent above the 1953/54 level and 18 per cent higher than that of 1949/50. (See table 25.)

Fortuitous influences rather than reconstruction policies caused the composition of agricultural production to undergo fairly significant modifications, which affected the region's domestic supplies more than production for export.

Production of bakery cereals—wheat and rye—expanded by 19 per cent, owing in the first place to excellent weather conditions for winter crops in the south of the region (Argentina, southern Brazil, Chile and Uruguay) and in Mexico, as well as, in the second place, to the application of wheat development measures in

Table 25. Latin America: Index of the volume of agricultural production
(1949/50 = 100)

	1950/51	1951/52	1952/53	1953/54	1954/55

Source: Official statistics.

most importing countries. Mexico became practically self-sufficient, and, despite consumption increments, the remaining producer countries were able to avoid increasing and, in some instances, even to reduce their imports.

Non-bakery cereals—oats and maize—registered a 6.5 per cent decline in relation to 1953/54, undoubtedly because of the sharp drop in Argentina's output of maize. Summer droughts, together with the deterioration of relative prices which for some time has been adversely affecting this crop, were partly responsible for one of the lowest volumes recorded in the last quarter of a century and for reducing exportable surpluses to a minimum. On the other hand, Cuba, which two years before had achieved self-sufficiency through the establishment of guarantee prices, had to restrict maize production by limiting the area under this crop, in view of the surpluses accumulated in 1953/54.

Fruit-growing, which had been steadily improving, achieved a significant position in 1955, when it contributed more than 10 per cent of the volume of Latin America's agricultural production. The output of tropical fruit (bananas and pineapples), traditionally produced for export, expanded by 8 per cent in relation to 1953/54 and by 23 per cent in comparison with 1949/50. Temperate-zone fruit, production of which progressed still more rapidly, not only completely satisfied increasing domestic demand, but became an important item in foreign trade.

Argentina harvested a record table-fruit crop and was able to export 77,100 tons in the first eight months of 1954/55, as against only 53,600 during the same period in the previous year. Its output of grapes, both for table consumption and for wine, registered a similar expansion: vineyards increased from a total of 170,000 hectares in 1949/50 to 207,000 in 1954/55, while production in the latter year, under excellent weather conditions, rose to 2.3 million tons.¹

Great progress in fruit production, mainly for export, was also achieved in Mexico, Chile and Uruguay. Both in the last two countries and in Argentina, however, exports were partially restricted by rising production costs and unfavourable exchange rates. The exchange reforms introduced at the end of 1955 will enable Argentina to compete on advantageous terms in the large market for fruit from the southern hemisphere represented by Europe and the United States.

The production of vegetables has also acquired great significance, although it is impossible to assess the extent of its development owing to lack of adequate statistics. Nevertheless, in view of the accelerated process of urbanization observable in most countries and the substantial demand for vegetables that accompanies higher income levels, it may safely be assumed that the rate of increase for such crops has been rapid.

Since coffee is of such great importance for the Latin American economy, particular emphasis should be placed on the fact that production of this commodity rose by almost 7 per cent in 1954/55. The fact that the harvest—totalling 2.22 million tons—was the largest recorded since the coffee crisis of the early 'thirties, mainly arose

from Brazil's exceptional output. Moreover, marked increments registered in Cuba, Mexico and Venezuela offset the serious declines caused by adverse weather conditions in Colombia, Ecuador and most of the Central American countries. In effect, the 1954/55 crop is the first to reflect almost completely the expansion represented by the new plantations incorporated in 1949 under the incentive of the steady rise in coffee prices.

In the region as a whole, significant decreases in production affected only a few agricultural sectors. Production of roots and tubers and of pulses declined by 3 and 4 per cent respectively, in comparison with the preceding harvests, but in both cases it was unfavourable weather that prevented the normal development of the crops. Conversely, the 3.5 per cent reduction in the sugar crop is particularly interesting both because it was brought about deliberately, and because the region's production for export and for domestic consumption followed divergent trends. To prevent a further drop in world market prices and the accumulation of larger surpluses,² Cuba and the Dominican Republic had to restrict their production by 7.4 and 3.3 per cent respectively. In contrast, other relatively important exporters expanded their output—Brazil by 6.5 and Mexico by 9.6 per cent, for instance. The increase in the Brazilian crop was due to the maintenance of guarantee prices at highly profitable levels. Venezuela stands out among the habitual importers with a 48 per cent increment in its sugar crop, which reached 144,000 tons and entirely covered domestic requirements.

The remaining sectors of Latin American production showed as a whole but little change, and, in most cases, small increments took place, in line with demographic growth.

A glance at salient developments in the various Latin American countries will complete the picture. Most interesting of all, from the national viewpoint, is undoubtedly the rapid progress achieved by agriculture in Mexico. An intensive government development programme, heavy investment in irrigation works and the rise in income—which created a very favourable domestic market for consumer goods—induced a rate of agricultural growth much more accelerated than in any other Latin American country, and comparable alone to that of some highly industrialized nations.³ In 1955, production attained a level 9 per cent above that of 1954, in which year the 1953 figure had in turn been exceeded by 18.9 per cent. The new increment meant not only that total and per capita production were respectively 36.5 per cent and 18.1 per cent higher than in 1950, but also that Mexico obtained record harvests of cotton, wheat, maize, barley, potatoes, sesame, cacao, sugar and tobacco, while cattle extraction substantially increased. A considerable improvement in domestic supplies was likewise involved, as well as larger exportable surpluses of certain products, especially cotton and sugar.

For Argentina's agriculture the year 1954/55 was one of recovery rather than of progress, in which it was able

² See section II of this chapter, on sugar.

³ Agriculture has developed more rapidly than any other economic sector in Mexico. Its gross product was 41 per cent higher than in 1950, whereas over the same period mining expanded by only 15 per cent, industry and building by 21 per cent and other activities by 23 per cent. The aggregate gross product increased by 26 per cent.

¹ In 1952/53, the production of grapes stood at 1.85 million tons, while in 1953/54 only 1.5 millions were produced.

to recuperate from the sharp decline caused by adverse weather conditions during the preceding year. Even so, agricultural production surpassed the 1953/54 level by 8 per cent and that of 1949/50 by almost 19 per cent. Factors contributing to this increment were the bumper wheat harvest (7.69 million tons), the considerable increase in wine production (65 per cent), which raised it to 1,757.6 million litres, or 21 per cent of the aggregate volume, and the recovery in cattle-breeding, the number of animals slaughtered having been only slightly less than in the peak year 1949/50. So high a level of meat production (9.5 million head slaughtered) enabled Argentina to regain its position among the main world exporters.

Despite such encouraging results, possibilities of expansion were limited by prolonged summer droughts which not only seriously damaged the maize harvest, but also affected potatoes, pulses and edible oilseeds. With respect to these last it should be mentioned that the unfavourable relative prices which have been affecting them for many years⁴ were even more responsible than in the case of maize for a still greater reduction of the area under cultivation. The outcome was a crisis in the production of edible oils, and 100,000 tons had to be imported. The case of Argentine oilseeds is one of the few in the whole history of Latin American agriculture wherein an important exporter has become an importer owing to internal price pressures.

Among the other developments of some significance for national or regional agricultural production, or directly influencing it, the following points merit some consideration:

(a) Venezuela became self-sufficient as regards rice. With an output of 73,000 tons, as against 43,900 in the preceding year, the country fully met its own requirements. The Government's development policy, and the substantial investment in the irrigation of land to be used mainly for this crop, ensure the future maintenance of this high level of production.

(b) Cotton cultivation in Central America continued to expand. El Salvador, Honduras and Guatemala registered increments in production ranging from 30 to 45 per cent with respect to 1954. The high yields obtained by the application of modern techniques, without recourse to irrigation, have resulted in low unit costs which amply compensate the price decline on the world market. The boom in cotton production has constituted a dynamic factor in Central America's agricultural development, and has involved the introduction of new and advanced techniques. During 1955 the area under cultivation in two countries—El Salvador and Guatemala—was extended by 22,000 hectares, thus reaching a total of 67,000 hectares. Nicaragua continued to grow cotton over 87,000 hectares. Nevertheless, by competing on advantageous terms, cotton has partially ousted other less profitable

crops, and has patently affected production of some basic foodstuffs, even to the extent of endangering the population's normal supplies.

(c) Uruguay virtually disappeared from the beef-exporting market. In the keen competition for land, cattle-rearing gradually lost ground to sheep-breeding and wheat-growing. Under the stimulus of the lucrative guarantee prices established by the Government, wheat encroached on about 250,000 hectares of land previously used for winter pasture and fattening; while the expansion of sheep-breeding exceeded the normal carrying capacity of the grazing-land used for this purpose, partly owing to the recent boom on the world wool market. Furthermore, the low prices paid to producers created marketing difficulties which were aggravated by the multiple regulations that restrict meat distribution in Montevideo. Consequently, beef production not only declined, but was diverted from its normal channels, and controlled meat exports were reduced to a minimum.

(d) The rate of agricultural mechanization slowed down in some countries to a degree which was particularly remarkable in Argentina, Brazil, Costa Rica, Honduras and Uruguay. In the first two and in the last of these the decline was due almost entirely to balance-of-payments difficulties and not to a weakening of demand. On the contrary, there is a substantial unsatisfied demand which in many cases has raised the prices of machinery and spare parts.

2. WORLD MARKET PRICES AND SURPLUSES

The over-all decrease in prices for agricultural commodities on the world market during 1955 constituted one of the depressive factors of most importance for the Latin American economy and undoubtedly the one whose repercussions most affected agriculture.

Since the accumulation of surpluses of basic agricultural commodities in the main producer countries of the world increased, while world demand remained relatively stationary—owing either to the trend towards self-sufficiency in importing countries or to consumers' unwillingness to pay the high prices quoted for some commodities—by the end of 1954 and the beginning of 1955 prices began to drop. The amount of the decrease ranged from 3.9 per cent for cotton on the London market to 35.2 per cent for cacao in New York. Prices for sugar and wheat—which had begun to fall in 1953—continued to decline during 1955, although at a slower rate. (See table 26).

Hence in 1955 the Latin American economy suffered a loss of about 550 million dollars on its exports which would have been avoided if the 1954 price level had been maintained. The dollar income obtained from exports of the six staple products—cotton, sugar, cacao, coffee, wool and wheat—amounted only to 3.016 billion dollars, that is, 21.2 per cent less than in the preceding year. This drop in foreign exchange earnings becomes more significant when it is recalled that the volume of exports of these six products increased by 8.4 per cent, and that one of the sharpest decreases affected coffee, which is, of course, Latin America's main export commodity and accounts for more than half the total value of agricultural exports.

⁴ In consequence of the unfavourable relative prices and the falling-off in yields, the relation of the gross income per hectare received by producers of maize, linseed, sunflower-seed and peanuts to that of growers of barley, rye, and, in a lesser degree, wheat and oats, deteriorated in 1954/55 by up to 50 per cent in comparison with income parities during the five years preceding the war. (See "The situation in Argentina and the new economic policy", *Economic Bulletin for Latin America*, op. cit., page 40, table 10.)

^m Pesos per 10 kilogrammes. Prices refer to average quotations in November.

Thanks to the policy of encouraging production which the Governments have now been pursuing for some time, or to the measures specifically adopted to counteract this price disequilibrium, the farmers did not bear the entire burden of the decline. Although official prices were pegged slightly lower than in the previous year, they were still profitable enough to maintain and even stimulate production. In addition to minimum prices—a widespread method of protecting many commodities—the Governments established export exchange rates closer to world parity, granted special bonuses and made purchases with public funds. In the case of coffee, international negotiations were also set afoot with a view to regulating the supply though no concrete results were achieved.

The International Wheat Agreement and the International Sugar Council played an important role in preventing prices for these products from falling still lower. Moreover, the policy of ensuring a specific price level for agricultural commodities adopted by the United States Government has had similar effects on international wheat and cotton quotations.

While certain domestic prices for export products fluctuated in accordance with price modifications on the world market—those of sugar, for instance, in Cuba, the Dominican Republic and Peru; of cotton in Peru; and of cotton and coffee in Central America—others, whether for the same or for different export commodities, diverged from the course followed by world quotations, largely as a result of official controls. Thus, while in 1955 the

average price quoted for "Santos" coffee on the New York market was 27.3 per cent lower than in 1954, the price received by planters in the state of São Paulo fell by only 7 per cent.

In isolated cases, such as that of cotton in Brazil or that of wool in Argentina, local prices rose considerably. The Government guarantee price for sugar meant that the Brazilian producer was paid 4,646 cruzeiros per ton, or 33 per cent more than in the preceding year. Cotton prices also improved by 26.3 per cent, as a consequence of the higher cruzeiro subsidy on exports resulting from the transfer of the exchange rate for this commodity from the second to the third category.

In the case of Argentina's wool, the modification of the exchange rate for exports effected in October 1955—from 6.25 to 18 Argentine pesos to the dollar (13.50 net)—led to an immediate rise in domestic market quotations which fluctuated between 51 per cent for fine crossbreeds and 160 per cent for medium crossbreeds. Conversely, the average world price was almost 8 per cent lower in 1955 than in 1954.

In addition, except for sugar, cacao and wheat, the price decline took place after most annual crops had already been sown, so that its direct or indirect depressive influence did not affect the 1954/55 harvests.

The accumulation of surplus stocks on the world market does not seem to have seriously handicapped Latin Amer-

ica's agricultural production in 1954/55. Only sugar production in Cuba and the Dominican Republic was directly affected, since the quotas established by the International Sugar Council obliged both countries to enforce further restrictions on sugar processing. As a result of this decrease in production and of the heavier exports effected by the four main producers (Cuba, the Dominican Republic, Brazil and Peru),⁵ surplus stocks were reduced to 2.3 million tons and their pressure on the market was

considerably eased. Stocks held in Mexico, on the other hand, rose to a level (310,000 tons) which is beginning to cause concern, since in present world market conditions the country cannot be sure of selling more than the 80,000-ton quota assigned to it by the Council. (See table 27.) Finally, the situation of the sugar sector in Cuba improved considerably thanks to the production of rich treacles and syrups, which in 1955 totalled 874 million litres and were all exported.

Additional sowings and the volume of the other crops produced mainly for export were not affected by the threat of marketing difficulties; on the contrary, production expanded substantially.⁶ As was previously noted, a large proportion of the exportable surpluses of the 1954/55 crop year was successfully sold on the world market, although at the cost of some price cuts and more frequent recourse to bilateral trade agreements, partial devaluation or special subsidies than in previous years. In cases where the situation seemed to be growing more serious, unforeseen events gave temporary relief. Argentina, which at the close of 1955 held a surplus of 1.9 million tons of wheat, harvested a small crop in 1955/56 (4.8 million tons) and will therefore have no great trouble in disposing of both the carry-over and the current exportable balance. Stress should be laid, however, on the increasingly keen competition which Latin America is facing from the United States' surplus liquidation programme in marketing its exportable availabilities of wheat. Although the programme operates outside regular trade channels, the large volume of sales and the exceptional payments facilities afforded have already perceptibly affected the demand for Argentine and Uruguayan wheat. More serious repercussions are expected

in the near future, not only on the demand of countries benefiting from such transactions, but also on the transport systems which serve normal commodity trade among the Latin American countries.

In Brazil, where the largest coffee harvest of the post-war period had been forecast for 1955/56, a major proportion of the crop—about 5 million bags—was destroyed by the frosts which ravaged coffee plantations in the state of Paraná in August 1955. This calamity, together with the smaller yields in some Central American countries in 1954/55 and the depletion of stocks on the United States market consequent upon uneasiness caused by the announcement of a possible devaluation of the cruzeiro, strengthened prices and averted, at least temporarily, the threat of a more serious deterioration of the market.

At the opening of the present coffee year,⁷ however, the surpluses situation was not clear. In July 1955, Brazil and Colombia held 390,000 and 216,000 tons respectively, or more than double the stocks on their hands at the same date in 1954. According to recent estimates, these stocks must be added to a world exportable production of 2.3 million tons.⁸ Since consumer requirements will probably fluctuate between 2.04 and 2.16 million tons (34 and 36 million bags), it is clearly pos-

⁵ Cuba sold 568,000 tons to the U.S.S.R. outside the Agreement. Brazil exported a total of 443,000 tons, so that the exportable balance at the end of the year was reduced to slightly over 160,000 tons.

⁶ If sugar and maize are excluded from the region's production for export, the index shows a rise of 8.5 per cent, instead of 3.2 for all commodities.

⁷ 1 July 1955—30 June 1956.

⁸ According to these estimates, Brazil's exportable surplus carried over to 1955/56 from the previous year will amount to 1.15 million tons, that is, 138,000 more than had been forecast.

sible that by the end of the year surplus stocks will have grown considerably.

The cotton situation, which during 1954/55 involved no serious problems in Latin America, seems to have deteriorated sharply at the beginning of the new cotton year (1 August), owing to imminent and progressive competition from the United States. In fact, this country has sold 138,600 tons to 19 countries, for delivery in 1956. Under the surplus liquidation programme, such purchases are payable in local currency and on long-term credit. Competition on such a scale, and the possibility of expanded world production in 1955/56, totally annul the headway made by Latin America in 1954/55, when the region's surplus stocks were reduced from 464,800 to 436,900 tons. Despite this somewhat gloomy outlook, Latin America's production of cotton has shown no signs of declining in 1955/56 and only Mexico has announced a sowing control programme designed to limit the area under this crop.

II. THE MAIN COMMODITIES

1. WHEAT

In 1954/55, the intensive wheat development campaign which a number of Latin American countries have been waging for several years seems to have scored its best successes to date. Most of the countries with adequate ecological conditions for economic wheat-growing made larger sowings and obtained good crops.

Production for Latin America as a whole reached one of its peak levels to date, namely, 11.9 million tons,⁹ which was 10 per cent higher than the figure for the previous year, and was partly attributable to an increment of 858,000 hectares in the area under cultivation,¹⁰ as well as to better yields in almost all countries.

This harvest enabled Latin America to make a significantly larger contribution to world production, since it accounted for 7.6 per cent of the aggregate tonnage, as against 6.3 per cent in 1954 and in the pre-war period. Its position as an exporter also improved, since its sales outside the region increased by 24 per cent in relation to 1954, reaching 2.2 million tons. Moreover, the two countries mainly responsible for this development—Argentina and Uruguay—also expanded their exports to certain Latin American importer countries by 27 per cent. These purchases, and local production increments, enabled the latter countries to reduce their imports from other regions to some extent. Latin America's net wheat exports, therefore, rose from 122,000 tons in 1954 to slightly over one million tons in 1955. (See table 28.)

Although the aggregate wheat imports of countries that are habitual importers registered only a minor contraction, the expansion of domestic production permitted a substantial improvement in the supply situation. Thus, in 1955 apparent consumption¹¹ rose to 6.45 million

⁹ Only the 1938/39 harvest was larger. Owing to Argentina's exceptional contribution of 10.3 million tons, Latin America's production slightly exceeded 12 million tons.

¹⁰ In 1955, the area under wheat in the whole of Latin America totalled 9.6 million hectares.

¹¹ For all Latin American countries except Argentina and Uruguay.

a Preliminary statistics.

tons, or 4 per cent higher than in the preceding year, when it amounted to 6.2 millions. According to these figures, per capita apparent consumption seems to have increased by 2.5 per cent.

The twelve producer countries which have to resort to imports in order to cover total consumption¹²—Argentina and Uruguay are the only countries with exportable surpluses—harvested 3.3 million tons in 1954/55, thus exceeding the previous year's level by 9.5 per cent and that of 1949/50 (which was 2.3 million tons) by 46 per cent. Chile accounted for a major part of this increment, since its production reached an unprecedented peak (1,078,000 tons), with a 16 per cent increase over the previous year. (See table 29.)

Several factors contributed to the excellent results obtained in Chile. Thanks to Government promises to fix a highly remunerative price level and the favourable situation created in 1954 by the 50 per cent subsidy on the price of fertilizers used for wheat-growing, 805,000 hectares (an area 6 per cent larger than in 1953/54) were tilled and sowed. The progressive improvement of techniques—particularly in connexion with the use of suitable strains and selected seed, the widespread employment of fertilizers and the steadily increasing mechanization of farming operations—as well as good weather conditions helped to determine a yield of 1,339 kilograms per hectare, one of the highest ever obtained in the country.¹³

Brazil continued to pursue its wheat development policy, and although deliveries of agricultural machinery were somewhat reduced on account of a decrease in imports, distribution of selected seeds and fertilizers increased,¹⁴ while the guarantee price of 7 cruzeiros per kilogramme was very favourable, representing a 40 per cent increment in relation to the preceding year.¹⁵

According to official statistics, the area under cultivation underwent practically no change, but the yields ob-

¹² Costa Rica, Cuba, the Dominican Republic, Haiti, Honduras and Nicaragua do not grow wheat and import all supplies required for consumption.

¹³ Yields per hectare had averaged 1,050 kilograms in 1935-39 and rose to 1,250 in 1950-54.

¹⁴ In the State of Rio Grande do Sul alone 10,400 tons were distributed as against 7,400 in 1953/54 and 2,100 in 1949/50.

¹⁵ At the time when this price was established—November 1955—Brazil was buying its wheat in the world market at 2.22 cruzeiros per kilogramme (at the official exchange rate of 25.82 cruzeiros to the dollar). However, conversion at the free exchange rate then in force would have raised the price to 5.76 cruzeiros.

^b Including El Salvador and Guatemala.

tained—906 kilogrammes per hectare, that is, 100 kilogrammes more than from the last harvest—enabled production figures to rise for the fourth consecutive time, a volume of 983,000 tons being attained. This new production peak is a result of Brazil's efforts to improve supplies of this cereal and to reduce imports. The 1954/55 crop was almost 13 per cent larger than that of 1953/54, and 85 per cent above the 1949/50 level while the pre-war volume was exceeded by 581 per cent.

Until very recently, however, even this accelerated growth of production had enabled a proportionate decline in imports to take place. In fact, purchases abroad continued to increase until 1953, and only during the last two years have imports been fairly constant at a level of about 1.65 million tons. This situation was due to the steady advance of per capita apparent consumption from an average of 30 kilogrammes during the pre-war period to almost 40 kilogrammes in 1951/55.

Wheat production also achieved significant progress in Mexico. Like the other countries, Mexico harvested a record crop of 881,000 tons, as against 839,000 in 1953/54 and an average of 573,000 in the five-year period 1949/53. Good crops during the last two years have made Mexico virtually self-sufficient. Imports, in fact, which in 1950 totalled 425,000 tons, declined to 9,000 in 1955.

The development of wheat production in Mexico has been furthered by the expansion of irrigated areas in the north, by the abundant water supply stored in irrigation systems during the last two years and by minimum price and official credit programmes. The most important factor, however, was the enlargement of yields through the use of improved seeds and fertilizers. Most of the wheat sown in 1955 belonged to the strains recommended by the Ministry of Agriculture, which distributed 23,000

tons of seed to farmers, that is, enough for 30 per cent of the total area. Consequently, yields have risen from an average of 884 kilogrammes per hectare over the five-year period 1948/52 to 1,070 kilogrammes per hectare in the last three years.

Among the other importer countries, only Peru seems to have achieved any expansion. Its production rose by 4.5 per cent, thus attaining a volume of 170,000 tons, despite the serious incidence of rust in the highland zones which constitute the main producing area. Through the ten years' unremitting research work of their experimental stations, the authorities have been able to obtain some strains which are sufficiently resistant to rust to warrant their cultivation. But Government services are still finding efficient seed distribution difficult, owing to a lack of access roads and because extension services are too limited. As a result, only 10 to 15 per cent of the farmers have benefited from the distribution of such seed.

Colombia pursued its policy of encouraging wheat production by maintaining the incentive of high prices and expanding genetic research programmes, but unfavourable weather conditions—particularly heavy rainfall—had a detrimental effect on production, which fell by 9 per cent to only 160,000 tons. Conversely, Ecuador seems to have increased its output by about 10 per cent, thanks to the energetic action of the Comisión Nacional del Trigo.

In the remaining countries—which for the most part do not possess large enough areas with suitable ecological conditions, and where wheat-growing has been fostered more or less artificially by protective government measures—a recessive process seems to have begun. The measures in question, particularly guarantee prices, were not as energetically implemented as in the past; the areas

under wheat and the volume of production have thus contracted to some extent. In Bolivia, Guatemala and Venezuela fairly substantial decreases were registered, while production seems to have remained stationary in Paraguay.

The high levels of wheat production, the substantial exports in 1955 and the prospects of continued production in excess of domestic requirements, qualify Uruguay as a large regional exporter.

Since the recent crop year witnessed the same profitable price as the previous year (16.50 Uruguayan pesos per quintal),¹⁶ the area sown and production reached new peak levels of 771,600 hectares and 853,600 tons, respectively.

Thanks to a 9 per cent increment in the area under wheat and to the excellent weather for winter cereals, in 1954/55 Argentina's production advanced substantially in relation to the previous harvest.¹⁷ A volume of 7.69 million tons was reaped, which is a record for the last 13 years.

In 1954/55, the combined production of Argentina and Uruguay rose to a total of 8.54 million tons. In addition to carry-over stocks from the previous crop, the available surplus stood at 9.85 million tons, so that, excluding the tonnage required for domestic consumption, an exportable surplus of 6.1 million tons was reached. (See table 30.)

The appreciable drop in world demand which is partly a consequence of increased domestic production in importing countries, the growing surpluses accumulated on the international market and the downward price trend all caused anxiety over the size of wheat availabilities at the end of the 1954/55 harvest. There were serious doubts whether stocks outside regular trade agreements could be sold without incurring severe losses in terms of prices or of wastage due to prolonged storage.

By August 1955, however, a pronounced improvement had taken place. Only 2.34 million tons remained unsold in Argentina and about 237,000 in Uruguay. Argentine stocks accounted for about 5 per cent of the aggregate surpluses accumulated by the four main exporters of the world, a peak 44.37 million tons.

¹⁶ At the basic export rate—1.51 Uruguayan pesos to the dollar—the price per quintal would stand at 10.99 dollars.

¹⁷ Production increased by 24 per cent in relation to 1953/54.

At the close of 1955, Argentina had shipped slightly more than 3.6 million tons, while Uruguay's 501,000 tons represented a record export level. Even before the close of the normal trade year adopted in Argentina (1 December–30 November) and on the basis of the world trade year (July–June), Latin America appeared to be recovering gradually its former position on the world wheat market. The region contributed 15.6 per cent of world exports in 1954/55 compared with 13.7 per cent in 1953/54 and 11.1 percent in 1949/50.

The bilateral agreements signed by both countries and the fact that they belong to the group of "inconvertible currency exporters" were of great assistance in selling crops and enabled large shipments to be made at the cost of minor price concessions.

During the first nine months of 1955, prices for Argentine and Uruguayan wheat exports declined in relation to the 1954 average. Argentina's exports, for example, averaged a price of 68 dollars per ton,¹⁸ against 69.70 in 1954. The 2.6 per cent decrease is slightly more than that which affected Australia and Canada, some of whose transactions are protected by the International Wheat Agreement, to which Argentina has not subscribed.

According to the scanty published information, a sharp reduction in Latin America's wheat production may be forecast for 1955/56. In Argentina, the incidence of anti-economic factors arising from official policy—mainly the maintenance of the same basic price as in the previous year—have caused changes in many farm programmes, with a consequent reduction in the cultivated area. Furthermore, bad weather prevented adequate soil preparation and caused a substantial drop in the area that could be harvested profitably. In November 1955, the new Argentine Government established modified price levels for wheat¹⁹ and other agricultural products. Although the new prices did not affect sowings, they may have encouraged a slight increase in the proportion of the harvested area and, even more important, provide greater incentives for future production.

In Uruguay, where the prejudicial influence of the high guarantee price established in former years began to be felt, the price was reduced from 16.50 to 14.00 Uruguayan pesos per quintal for producers farming more than 250 hectares. This measure had the desired effect since production declined to 820,000 tons.

The wheat crop was seriously damaged in Chile by adverse meteorological conditions of various kinds and the harvest is thus expected to be some 100,000 tons lower than in 1955.

The lower volume of production in the Latin American exporting countries during 1955/56 will reduce, at least temporarily, the many problems arising from marketing abroad. The growing surpluses on the world market, the steady downward price trend and, in particular, the sale of United States wheat, by virtue of the programme for liquidating surpluses under very favourable terms for purchasers, all suggested many problems in selling the region's exportable balances.

¹⁸ Converted at 5 Argentine pesos to the dollar, the prevailing rate for wheat exports during the months in question.

¹⁹ The new price was pegged at 70 Argentine pesos per quintal, representing a 40 per cent increase.

But the sharp decline in Argentina's present crop has made it necessary to stop the sale of some of the unsold stocks remaining from the previous harvest, in order to meet commitments. Argentina will thus be unable to deliver the 1.2 million tons stipulated in the 1955 agreement signed with Brazil and negotiations have begun to reduce such exports to 900,000 tons. As a consequence, Uruguay has benefited indirectly from this situation, since the entire harvest could be sold.

Nevertheless, the future outlook is uncertain, particularly in view of the competition from United States wheat. Uruguay is considering a further reduction of the guarantee price level in order to limit the area under this crop. Argentine is confident of its competitive market position on the basis of the quality of its wheat.

2. MAIZE

Mainly as a result of poor Argentine harvests, Latin America's maize production dropped substantially in 1954/55. Total output of 17.5 million tons represented a 14.1 per cent decline in relation to 1953/54. But, if Argentina is excluded, slight progress has been made by the rest of Latin America—14.98 million tons as compared with 14.8 millions—even though the increase did not suffice to maintain the same per capita level as in 1953/54. (See table 31.)

^a Provisional statistics.

In view of declining yields, priority has been given to the improvement of strains and farming methods. Most countries have achieved good results by introducing selected varieties, while, at a later date, hybrid maize strains have been developed which have raised yields by 50 per cent in some cases. Production of these strains has already gone beyond the experimental stage and they are being reproduced commercially in Brazil, Chile, Colombia, Mexico, Peru, Venezuela and other countries. Except for Chile, however, where maize is relatively unimportant, the use of hybrid seed has not become as widespread as might be expected. (See table 32.)

In 1954/55, the maize crop in Argentina dropped to one of the lowest levels during the post-war period; production of 2.5 million tons represents decreases of 43 and 70 per cent in relation to 1953/54 and the pre-war period (8.2 million tons), respectively. The summer drought caused so much damage that only 62 per cent of the area under maize could be harvested; under normal conditions this proportion is never below 70 per cent. Unfavourable relative prices, however, represented

^a In addition, 4,250 tons of seed improved by free pollination were produced.

^b Agricultural year 1955/56.

^c Improved and hybrid seed.

the decisive factor in this sharp reduction, because they have resulted in the displacement of maize by more profitable crops since the mid-forties. Moreover, ever-lower yields caused by the progressive impoverishment of the soil in Argentina have aggravated the situation. While in the period 1929/30-1931/32 an average 1,980 kilogrammes were obtained per hectare, in 1951/52-1953/54 the yield dropped to 1,592 and declined still further to 1,370 in 1954/55. As a result, the area under maize contracted from an average of 6.7 million hectares in 1933/34-1937/38 to only 3.2 and 3.0 millions in 1953/54 and 1954/55 respectively. The small volume of the 1954/55 harvest not only limited maize exports to 375,000 tons, against 2.2 millions in 1954, but also influenced shipments of oats, a higher proportion of which were required to cover the deficit in animal feed stocks.

In Cuba, where production had been stimulated by guarantee prices and some surpluses have accumulated, such prices had to be reduced in order to restrict sowing. The result was immediately apparent, since production amounted to only 178,000 tons, or 25 per cent less than in 1953/54.

Bad weather damaged sowing and yields in Colombia, Ecuador, Uruguay and Venezuela and the production of these countries thus declined somewhat. Thanks to a small expansion of the cultivated area and better yields, Brazil obtained a crop which was 2 per cent above that of the previous farm year. Although this harvest constituted a record for Brazil, minor imports were necessary to cover the demand of large centres where production was inadequate. Thus the paradoxical situation arose whereby, owing to the lack of transport, very low prices were quoted for maize and the crop was wasted in some productive areas (Triángulo Minero, Goias, Matto Grosso, etc.), while large consumer centres arranged imports from the United States.

The increasing use of genetic seeds in Chile led to a substantial improvement in yields and a record harvest (102,400 tons) which was 40 per cent above the 1953/54 level.

Mexico's production expanded to 4.7 million tons and imports were virtually unnecessary, since only 900 tons were received as compared with 144,000 in 1954 and 373,000 in 1953. Abundant rainfall, minimum price lev-

els and official credit programmes²⁰ all contributed to the betterment of domestic supplies. The effects of the improved seed programme—sponsored by the Comisión Nacional del Maíz, which delivered 5,400 tons of hybrid maize seed to farmers—is beginning to be felt.

There were some domestic maize shortages in Central America during 1955, particularly in the first six months, owing to the poor crop of 1954 which was 14.5 per cent lower than in 1950 and 12 per cent below the 1949-53 average. Guatemala—which had become self-sufficient some years ago and had even exported some tonnages to El Salvador and Mexico—encountered domestic problems which had serious repercussions on the agricultural scene. The cultivated area contracted and an output of 368,000 tons (against an annual average of 432,000 in the period 1949-53) proved inadequate to cover consumer requirements. Hence, before the 1955 harvest began to enter the market, it was necessary to import 337,000 tons of maize. This tonnage, mainly purchased from the United States and Mexico, undoubtedly represents the peak import figure for the last ten years.

The traditional disequilibrium in El Salvador between natural resources and the population became more acute as a result of the poor harvest in 1954; it was aggravated by the expansion of cotton production which obliged the farming of cereals to be shifted to marginal and low yielding land. In 1955, therefore, imports of maize, which is the basic foodstuff in El Salvador's diet, rose to 42,000 tons from 23,700 in 1954 and an average of 13,000 annually in the period 1950-53. For the first time in many years Honduras was obliged to import maize because of damage caused by hurricanes and floods. These imports totalled 3,000 tons and were mainly used to offset exports to El Salvador despatched between November 1954 and April 1955. It was also unique during the recent past that Costa Rica's harvest was insufficient; 7,000 tons of yellow maize for the manufacture of feed concentrates had to be imported from the United States. Nicaragua

was the only Central American country where imports were unnecessary in 1955, although exports to El Salvador declined sharply when the replacement of maize by cotton in the traditional farming areas of the Pacific zone caused production to fall.

The situation will probably alter significantly in 1956. Guatemala harvested 463,000 tons of maize in 1955, or 7 per cent higher than in 1949-53, so that domestic requirements will probably be covered without recourse to imports. Production in Honduras and Nicaragua has been satisfactory; it is expected to supply the entire domestic market and to raise the traditional exports to El Salvador. Conversely, it is thought that a peak level of 46,000 tons will be reached by El Salvador's imports, since the 1955 harvest was even smaller than that of the previous year.

3. RICE

Rice is undoubtedly one of the crops which has developed most rapidly in Latin America. Without exception, all the countries of the region grow rice and most of them have more than doubled their production since the pre-war period; some—Chile, Ecuador, Mexico, Uruguay and, more recently, Venezuela—have attained complete self-sufficiency and even exported small tonnages. The 1954/55 harvest, representing 5.6 million tons of unpolished rice, surpassed the previous year by 10.8 per cent and stands 200 per cent above that of 1933/34-1937/38. The previous trends in rice production has thus been reaffirmed. The exceptional progress is still more remarkable when it is compared with the evolution of this crop elsewhere in the world. In fact, world production in 1954/55 was 4 per cent lower than in the previous year and barely 7 per cent higher than in 1933/34-1937/38. (See table 33.) In 1954/55 Latin America accounted for 3.4 per cent of world output which compares favourably with the 1.2 per cent in the pre-war period.

Table 33. Latin America: Rice production

^a Excluding the Soviet Union.

The accelerated development of rice production has steadily covered an increasing proportion of the requirements for domestic consumption, while imports have dropped from an average of 390,000 tons in the pre-war period to some 214,000 tons in 1954. Imports for 1955 are as yet unknown, but in view of the sharp production increment they cannot have exceeded 190,000

tons. Hence, imports have almost certainly declined by over 50 per cent between 1934-38 and 1955.

The rise of almost 550,000 tons in Latin America's rice production since the 1953/54 crop was mainly based on Brazil, where the rice output grew from 3.36 million tons to 3.92 millions in 1954/55. Brazil has thus recovered its share of regional production in the pre-war period and in 1949/50 by contributing 70 per cent of the aggregate instead of only 63 and 66 per cent in 1952/53 and 1953/54, respectively. Progress by Brazil was mainly

²⁰ From December 1944 to June 1955, guarantee prices for maize rose steadily in Mexico. The increase in average prices ranged from 12 to 16 per cent and partly offset the unfavourable effect of devaluation on the relative prices of maize.

attributable to better yields, to good weather in the main production centres and to the use of better farming techniques which are becoming widespread in rice-growing areas.²¹

Brazil was formerly the main rice exporter of Latin America. Nevertheless, for a variety of reasons, particularly low prices on the world market and the unfavourable exchange rate for exports, shipments abroad declined rapidly and disappeared altogether in 1954. Substantial surpluses thus accumulated in the State of Rio Grande do Sul, which were purchased by the Government for export in 1956 when a more favourable exchange rate was established.

Venezuela is outstanding as a country where rice production has developed rapidly, increasing from 13,000 tons only in the pre-war period to 49,000 in 1953/54 and to 73,000 in 1954/55.²² The vital elements contributing to the expansion were, on the one hand, technical and economic aid given to farmers by the Corporación Venezolana de Fomento by means of a special rice development programme initiated in 1949 and, on the other, the establishment of minimum guarantee prices by the Banco Agrícola y Pecuário. Since self-sufficiency has been attained, efforts are now being aimed at consolidating the situation. To this end, attempts are being made to transfer crops at present grown on unirrigated soil, with low yields and high production costs, to irrigated land. This transposition will be achieved gradually by means of settlement programmes.

Production also increased considerably in Ecuador, reaching 70,000 tons in 1955 and thus recovering the previous level, which had dropped to only 46,000 tons in 1954. Nevertheless, exports from Ecuador could not be

raised above the 1954 level (about 20,000 tons) because world prices were depressed.

In 1955, Chile obtained its peak production during recent years, slightly more than 93,000 tons, which was occasioned by better yields²³ and to an expansion of some 10 per cent in the cultivated area.

In Mexico, 178,000 tons of rice were harvested as compared with 170,000 in 1953/54 and over 180,000 in the period 1948/49-1950/51. Domestic supplies were thus ensured and approximately 20,000 tons, in addition to 17,000 remaining from the previous crop, will be available for export.

Cuba's rice crop remained very similar to that of 1954 (173,000 tons). Planters have had to face various problems, *inter alia*, a lack of water for irrigation, brackish water, loss of soil fertility and reduced credit availabilities. Production levels during recent years, however, have reduced the dependence of Cuba—the major rice importer of Latin America—on purchases abroad. In the period from August 1954 to July 1955, Cuba's imports from the United States (85 per cent of aggregate purchases) totalled only about 154,000 tons against 215,000 obtained from the same source in the period before 1954.

4. SUGAR

Approximately 10 million tons of sugar were produced in Latin America during 1954/55, a tonnage slightly inferior to that of 1953/54 (10.4 million) and the lowest for the region in the past five years. (See table 34.)

The reduction may be attributed almost entirely to the additional fall of 363,000 tons in Cuban production. Relative decreases also occurred in Argentina, Colombia, the Dominican Republic and Ecuador. Conversely, production in Central American countries as a whole, in Brazil, Mexico, Peru and Venezuela moved upwards.

²³ From 2,930 to 3,110 kilogrammes per hectare.

Source: Official statistics.

These trends reflect to a great degree the various factors which have influenced sugar-producing activities in Latin America, both in the traditional exporting countries and in those which import or occasionally export sugar. In fact the aggregate production of Cuba, the Dominican Republic and Peru—which belong to the first group—fell for the third consecutive year since 1951/52.²⁴ On the other hand the countries of the second group have shown steady progress in the last five years. But in 1954/55 the over-all increase was slight owing to lower Argentine production caused by a heavy frost which destroyed many plantations.

Cuba, the main Latin American exporter, faced many problems arising from market conditions and the surpluses accumulated in previous years. Consequently sugar processing was restricted to 4.5 million tons. This figure is the lowest for the post-war period, representing a 7.4 per cent decline in relation to 1954 and 27.3 per cent below the peak production obtained in 1952. Parallel to these successive decreases, the processing of rich molasses and syrups has helped to relieve the situation. The manufacture of these commodities had ceased in 1944, but was re-started in 1954 when 495 million litres were produced for export. In 1955, production totalled 874 million litres, which were also placed on the international market.

The Dominican Republic also restricted production, although to a minor degree. Peru is the only country among the traditional exporters which has not only maintained the high production level of 1953/54 but has also failed to encounter any major problem of surpluses. Production increments attained by Peru in the last few years have mainly been derived from better unit yields, thanks to the adoption of modern cultivation techniques for sugar cane. The degree of efficiency in processing and the higher yields allow Peruvian sugar to compete on the world market without any State protection.

Among the countries which grow sugar mainly for the domestic market, recent years have witnessed major effort to expand production and remarkable increases have been achieved in some cases. Brazil and Mexico, for instance, after attaining self-sufficiency, now face the problem of accumulated surpluses with no easy outlet to the market.

The situation in individual countries merits more detailed analysis. Mexico's sugar expansion continued in 1955 when 910,000 tons were produced, in contrast to 830,000 in the previous year and an average of 637,000 in the five-year period 1949-53. Apart from the self-sufficiency attained since 1947, the uninterrupted growth of production has allowed Mexico to enter the export market. Stocks have increased steadily since 1952 and have exceeded normal reserve levels for the domestic market; the surplus problem has thus appeared in Mexico. Sugar production in 1955 provided an exportable balance of some 106,000 tons, which, added to carry-overs from previous years, placed reserve stocks at the peak level of 310,000 tons in December 1955. To appreciate the gravity of the situation it should be recalled that under

the present conditions for the world sugar trade, Mexico can only rely on a sure market for 80,000 tons.²⁵

Encouraged by minimum prices compatible with the costs for marginal producers, sugar production in Brazil has grown at a higher rate than consumption. The São Paulo area accounted for most of the increment. In 1954/55, 2.1 million tons were produced, or 6.5 per cent above the previous year and 31 per cent higher than the average for the five-year period. As in former years substantial tonnages of cane were used to manufacture alcohol, which prevented sugar output from being even greater. Deducting domestic requirements of 1.8 million tons, the recent harvest provided an exportable surplus of almost 300,000 tons.

Venezuela was able to cover domestic requirements in 1955. Production amounted to 144,000 tons, in comparison with 99,000 a year previously and an average of 66,000 for the preceding five years. Expansion of sugar production constituted one of the basic programmes sponsored by the Corporación Venezolana de Fomento in co-operation with the Ministry of Agriculture. The Corporation encouraged sugar-cane planting by providing credits and expanding processing facilities through the installation of five new mills and the extension of another. In addition, the Ministry of Agriculture has pursued profitable research activities connected with genetics and has thus achieved a substantial rise in unit yields. The subsequent harvest is at present a matter for concern, since it will probably provide a surplus of 50,000 to 60,000 tons. Nevertheless, it is thought that measures to limit uncontrolled productive expansion and others aimed at raising consumption may obviate the risk. Otherwise the situation may be serious, because high production costs in Venezuela do not enable the surpluses to be sold abroad.

The sugar production programme was successfully implemented in Uruguay. Production rose to 37,700 tons against only 20,600 in the previous year and 3,000 tons in 1949/50. Current output supplies about 40 per cent of domestic consumer requirements.

Any consideration of prices on the world market must draw a distinction between free-market quotations and United States prices.²⁶ On the free market, the downward trend was halted, a trend which had begun in 1954 when the average price on the New York free market dropped by 3.7 per cent in relation to the 1953 average. In 1955 the decrease only represented 0.7 per cent in relation to 1954. On the other hand, the decline was far greater on the United States market—3.8 per cent—and reflected the downturn of prices for all foodstuffs in that country. Should this decline continue, it may be of importance for Latin America, inasmuch as a large share of Cuba's production is destined for that market, as well as various quotas from other countries.

More sugar was exported from Latin America in 1955 than in 1954 in terms of both volume and value. (See table 35.)

²⁴ In reality, the decline was due to the sharp reduction in Cuba's production, since the Dominican Republic had a smaller harvest only in 1954/55, while production in Peru has risen steadily.

²⁵ At the session of 1 June 1955, the International Sugar Council established the Mexican export quota at 69,800 tons and to which must be added the tonnage sold on the United States market (11,000 tons).

²⁶ See again table 26.

Source: Official statistics.

^a Provisional figures.^b January-September.

Two main factors apparently contributed to the increment. Firstly, the U.S.S.R. purchased 568,000 tons from Cuba at the beginning of the year; secondly the recovery of Brazilian exports was determined by the adoption of a special exchange rate of 50 cruzeiros to the dollar, which allowed Brazilian sugar to be sold at competitive prices and outside the commitments of the International Sugar Agreement. The Brazilian Government advised the Council that, as it was not a party to the Agreement, it was not bound by the stipulations. This position was adopted because Brazil did not believe its quota was commensurate to its export requirements.

Because exports were greater and the production of exporting countries declined in comparison with the previous year, the situation of sugar surpluses in the region did not deteriorate. Certain countries, however, are still confronted with difficulties for the sale of their exportable surpluses. By the close of 1955, these stocks had reached 2.3 million tons, which is 10.8 per cent less than at the same date in 1954. In Cuba, the surpluses fell by 322,000 tons (from 1.95 to 1.62 million tons at the end of 1954 and 1955, respectively). In the Dominican Republic, accumulated reserves declined by 21,000 tons and remained at only 54,000 tons in 1955. Only in Mexico did surpluses increase—from 203,800 to 310,000 tons.

Although the surplus problem is still unsolved, most Latin American producers continue to encourage projects for the development of the sugar industry. For example, two new mills—each with double the capacity of any existing plant yet established in the country—are being built in the Dominican Republic. In addition, cane is being planted in areas (estimated at 28,000 hectares) which were formerly under rice.

It is estimated that in Mexico—according to present processing capacity and the sowing which is being undertaken—production may rise to 1.5 million tons in the near future. The increase in sugar production originated in a plan begun in 1950 with a target of 1 million tons by 1960 which was virtually attained in 1955.

Bolivia, which relies largely on sugar imports, has announced that the sugar mill in construction at Montero will enter operation in May 1956 and that a further plant will soon be built.

Chile is a newcomer to regional sugar production. Work has already begun on the construction of a second

beet-sugar processing plant in the Llanquihue area. The addition of this mill, with an annual processing capacity of 20,000 tons of sugar, will raise aggregate installed capacity to 40,000 tons annually.

Countries which only produce for domestic consumption have achieved an expansion of output principally through the guarantee price policy adopted by governments. Thus sugar production in Uruguay and Venezuela is heavily subsidized by consumers and the State. Guarantee prices are also paid to farmers in Bolivia, Brazil and Chile.

5. COFFEE

According to preliminary estimates of Latin American coffee production for 1954/55—based on official figures published by some countries before December 1955—the volume of the harvest amounted to 2.04 million tons. A later revision of the production figure in Brazil, however, in the light of the export volumes registered by the Instituto Brasileiro do Café, raises the over-all level of production in Latin America to about 2.2 million tons. This constitutes a record, since it is almost 15 per cent higher than in the previous year and 7 per cent above the 1934-38 average. (See table 36.)

Not only did the weather favour high yields in the main producer countries, but this was the first year when production began to reap the full benefit of the new coffee plantations opened up in the late 'forties under the stimulus of a rise in coffee prices which had been practically uninterrupted since 1946. The exact extent of the area at present under coffee is not known, but it is estimated that in 1955 more than 150 million new trees entered full production. All producer countries, but particularly Brazil, Cuba and some Central American countries participated in this development. Despite the price decline of 1954, plantations have continued to expand, although at a much slower rate.

The good harvest obtained in 1954/55 for marketing during the 1955/56 coffee year upset the short-lived balance between supply and demand; surpluses again began to accumulate in the main producer countries. The reduction of almost 138,000 tons in United States consumption during the trade year which closed on 30 June 1955 contributed to an increase in the unsold stocks held by Brazil and Colombia. Data on other countries are unavailable, but such stocks are presumed to have

^a Estimate taken from *Foreign Crops & Markets*, Vol. 71, No. 23 (5 December 1955).

^b Costa Rica, El Salvador, Guatemala, Honduras and Nicaragua.

been negligible. In the two instances given, however, they rose in the aggregate by 234,000 tons (3.9 million bags) in relation to the same date in the previous year, thus reaching a total of 606,000 tons (10.1 million bags), of which the Brazilian Government bought and withdrew from the market an estimated 192,000 tons (3.2 million bags.)

Information on coffee-roasting in the United States during the current coffee year (1955/56) indicates a decided recovery in that country's consumption. The marked expansion of Brazilian and Colombian exports to Europe and the rest of the world also reveals a patent trend towards a return to the 1953/54 levels. Nevertheless, even if world consumption should attain the same volume as in that year—1.98 million tons—surplus stocks at the end of the present trade year (30 June 1956) will exceed those held on the same date in 1955 by the least 180,000 tons. Part of this surplus, however, may be incorporated into the normal reserves accumulated by consumer countries to facilitate distribution.

The frosts which ravaged the coffee plantations in the State of Paraná, Brazil, in August 1955, temporarily eased the problem of coffee surpluses by wiping out practically the whole of the large increment in Latin American production (from 240,000 to 300,000 tons) forecast for the 1955/56 harvest. Before this contingency, bad market conditions and the threat of their deterioration with the sale of the 1955/56 harvest induced Latin American coffee producers to hold several meetings at which they agreed to establish an International Coffee Bureau and to prepare an emergency plan to meet the situation. The agreements included the creation of buffer stocks to prevent violent price fluctuations and the expansion of world consumption through the technical and economic collaboration of the member countries. As a first step, the emergency plan provided for the establishment of export quotas for the 1955/56 coffee year and recommended that stocks should be sold only at prices ranging from 50 to 60 dollar cents per English pound c.i.f. New York. Moreover, it was resolved to continue or to organize the financing of stocks, while other measures of a purely local character were adopted. The weakness of this undertaking was that the agreements were concluded by producers and not by Governments, and

in addition non-Latin American producers did not attend the meetings; hence the efforts proved abortive. At a later date, the Ministers of Finance of Colombia and Brazil met to reach more definite accords; but, in view of the frosts which affected Brazilian production at that precise moment, the Ministers confined themselves to issuing a statement that the losses caused by frost had restored the statistical balance of production, and to adopting preliminary resolutions for dealing with future emergencies. They also agreed, among other measures, to guarantee adequate price supports for the planters and not to encourage production in areas unsuited for the crop.

If production is analysed by countries, Brazil stands out as the leading contributor to the increment registered in Latin America during 1954/55. In fact, the production level is estimated to have reached at least 1.32 million tons,²⁷ that is, 27 per cent above the previous year's level and 17 per cent higher than the peak post-war crop registered in 1952/53. The size of the harvest may be attributed to the following causes: (a) excellent weather conditions in most of the major production areas, which permitted yields very similar to that of the preceding year or even larger, although 1954/55 corresponded to the downswing in the biennial production cycle; (b) the entry into production of more than 100 million coffee trees from three to five years old, many of which had been damaged by the frosts that had affected production in the preceding year; (c) the fact that most of these coffee trees are planted in very fertile virgin soil, in areas which were reclaimed specifically for coffee cultivation; (d) the increasing use, in modern plantations, of new high-yielding strains, particularly

²⁷ According to the provisional figures published by the Production Statistics Service of the Ministry of Agriculture, the coffee crop seems to have amounted to 1.17 million tons. But estimates made by the Instituto Brasileiro do Café and by the Department of Agriculture of the State of São Paulo—on the basis of the coffee registered for export on the books of the former organization up to 20 January 1956—bring exportable production up to 1.2 million tons (20 million bags). Since domestic consumption cannot be less than 180,000 tons (3 million bags), this would mean that the volume of production was 1.38 million tons (23 million bags). The figure calculated by the United States Foreign Agricultural Service, namely, 1.32 million tons (22.2 million bags), can be given as a conservative estimate.

"Novo Mundo" and "Bourbon Amarelo"; and (e) better farming practices, which, though applied on a small scale, are giving very satisfactory results.

Practically 80 per cent of the increment in Brazil's production was accounted for by the State of Paraná, where the 1954/55 crop was three times larger than the previous year's (rising from 117,600 tons to almost 360,000).²⁸ It was in this State that plantations were extended to the limit of available labour, capital and transport facilities, by the utilization of vast tracts of highly fertile land known as "terra roxa".²⁹

The Paraná coffee-growing district, however, seems to lie on the climatic borderline for this crop, and twice already (in 1953 and 1955) plantations have been devastated by quite severe frosts. The last seems to have seriously damaged about 75 per cent of the area under coffee. According to official estimates, production in 1955/56 will fall below 60,000 tons (1 million bags), which would imply a loss of approximately 300,000 tons. Despite these setbacks and the fall in the price of coffee, planting has continued, although at a slower rate than two years ago.

The coffee sector's income improved in the last agricultural year, not only because of the larger volume harvested, but also on account of the Government's policy of guaranteeing planters a minimum price. The minimum dollar price for exports was reduced, the exchange rate for coffee was devaluated—by transferring it from the first category (31.5 cruzeiros to the dollar) to the second (37.06 cruzeiros to the dollar)—and large stocks of coffee were purchased through the Production Financing Service.

Available data on Colombia are to some extent contradictory, but, to judge by exports statistics and various isolated figures, production may be estimated at 424,000 tons, which is 5 per cent above the previous year's level.

The unfavourable effects on the country's economic activities produced by the drop in world coffee prices and the decline in exports during the last quarter of 1954 and the first half of 1955, induced the Colombian Government to advocate a policy of protection for the coffee sector. Among other measures, a minimum price for coffee was established, and the Federación Nacional de Cafeteros was authorized to buy up the whole of the output on the Government's behalf. This organization was able to draw upon the resources of the Fondo Nacional del Café and upon credit granted by the Banco de la República. The exchange rate for coffee was also raised from 2.38 to 2.5 pesos to the dollar.

Unseasonable weather in the coffee areas of Mexico caused a small crop of only 80,400 tons, representing a decrease of 13.6 per cent in relation to that of the preceding year. Nevertheless, it should be recalled that the area under coffee has continued to increase thanks to the development programme of the National Coffee Commission. Between May and July 1955, the Com-

mission distributed, free of charge, 3.2 million coffee trees and a great deal of selected seed.

In the Central American countries, rains in February and March resulted in early flowering which were later ruined by drought. When the rainy season set in steadily, the trees flowered again, with the result that the crop ripened unevenly. Consequently, harvesting was prolonged, costs rose, the quality of the beans deteriorated and the income of the planters was adversely affected. Thus the harvest amounted to only 182,000 tons, and failed to equal the preceding year's record crop of 205,600 tons.

Cuba, which in recent years had barely managed to supply domestic requirements, produced 46,500 tons in 1955—in contrast with only 38,600 in the previous year—so that an exportable surplus of 7,000 tons was obtained.

The marketing of Latin America's coffee production had entered a phase of definite deterioration at the beginning of 1954 and no prospects of improvement came into sight until mid-1955. Prices had fallen sharply and exports had declined to their lowest level in recent years. As from June, however, the situation improved appreciably. Prices partially recovered, and exports to the United States, particularly from Brazil, increased at a rapid rate. By the end of 1955, Latin American exports had reached 1.52 million tons and exceeded the previous year's volume by 16 per cent.

The circumstances which brought about this situation may be summarized as follows:

(a) Coffee prices began to fall in April 1954 and continued to do so until June 1955, owing to lower consumption levels and a considerable decline in exports, to an over-estimation of supply and to the hope entertained by consumers that the cruzeiro would be still further devaluated and that the dollar price of coffee would thus be reduced. In consequence of a smaller volume of imports, supplies of coffee beans in the United States dropped to the lowest level recorded since 1948—86,400 tons on 30 September 1955—while consumption little by little reverted to normal in 1955. The combination of these two factors brought about a marked rise in demand, reflected in the rapid increase in imports during the second half of the year. (See table 37.)

(b) European demand for coffee from Latin America—especially from Colombia—also expanded considerably, thus helping to account for the region's heavier exports.

(c) The great demand for Colombian coffee resulted in so considerable a reduction of consumer stocks in the main importing countries that mild grades were to some extent in short supply. Consequently, quotations for Colombian coffee on the New York market exceeded those for Brazilian coffee by a larger margin than usual.³⁰

(d) Exports from other Latin American countries rose by 10 per cent, a development for which Costa Rica, Mexico and Nicaragua were mainly responsible. African exports, especially to the United States, also increased.

²⁸ Up to 20 January 1956, the Instituto Brasileiro do Café had already registered 310,000 tons (5.2 million bags) from the State of Paraná.

²⁹ According to a study made by the Instituto Brasileiro do Café, in 1955 there were about 720 million coffee trees in the State of Paraná.

³⁰ The usual difference between prices for Manizales and Santos grades is about 4 dollar cents per pound; in the final months of 1955, the difference exceeded 14 cents per pound.

Despite the improvement in the export situation during the latter part of 1955 and first months of 1956 and the return to normal of United States consumption, the outlook for the future does not appear very promising unless arrangements for the control of the market are agreed upon among all producer countries. As was indicated, the decline in United States consumption left an exceptionally large surplus in the two principal producer countries. Despite the considerable expansion in consumption during the present year,³¹ it is probable that by June 1956 the excellent crop just harvested will leave a surplus in Brazil and Colombia which may well amount to about 600,000 tons (10 million bags).

It should be recalled that the possibilities of expanding production over the medium term are directly linked not only to the production of new plantations, but also to the prospects of obtaining higher average yields, especially in Brazil, by virtue of improved farming practices and the fact that, on the average, the new plantations will have reached their phase of highest productivity.

6. COTTON

In 1955, the region's cotton output again reached a record level of 1.22 million tons—which was 5 per cent higher than the preceding year's and 23 per cent above the average for the last five years. Moreover, these levels represent an 80 per cent improvement in relation to the regional average during the pre-war period. Thus, the proportion of world production for which Latin America was responsible rose from 9.8 to 16.7 per cent between the pre-war period and 1955.

³¹ Coffee year 1955/56.

In the year under consideration, as before, Mexico and the Central American countries accounted for most of the increment. Their share in the regional aggregate is now 556,000 tons or 45.6 per cent, which compares very favourably with the 75,300 tons (12.7 per cent) which they contributed in the pre-war years. On reaching the 461,000-ton mark in 1955, Mexico became the main Latin American producer, displacing Brazil from this position. Mexico's production in 1955 should be compared with the volumes of 390,000 and 260,000 tons attained in 1954 and 1950 respectively. (See table 38.)

Cotton cultivation has developed rapidly in Mexico during recent years on the new land reclaimed by irrigation. Apart from the expansion of the area under cotton, unit yields have improved from 347 kilogrammes per hectare in 1949-53 to 462 in 1955, particularly through the decline of dry-soil planting and to a more widespread use of fertilizers. It is in the areas under cotton that the most advanced techniques are applied, and machinery, fertilizers, insecticides and weed-killers are extensively utilized.

The last crop left Mexico with an exportable surplus of about 380,000 tons. As a result of strong competition from United States cotton on the world market and of the fact that world production has been increasing at a faster rate than demand, the Mexican Government has decided to restrict expansion. To this end, it will control sowing during the next season.

Although Central America produces less cotton than Mexico, development has been even swifter and more

spectacular. In 1948 production barely reached a level of 6,000 tons, but in 1955 it had advanced to 92,800. The 1955 crop was 18 per cent larger than the preceding year's and almost one-and-a-half times greater than the average volume of annual production during 1950-54. While in 1954 the country which contributed most to the enlargement of Central America's cotton output was Nicaragua, where production practically doubled in 1953, in 1955 planting increased most intensively in El Salvador and Guatemala. In the former, the area under cultivation grew from 29,000 hectares in 1954 to 46,000 in 1955, and in the latter from 16,000 to 21,000 hectares. On the other hand, the area under cotton in Nicaragua remained practically stationary at about 87,000 hectares.

The post-war period of high cotton prices constituted the main incentive to the expansion of this crop in the Central American region. But even when prices fell sharply, the high yields obtained—which are among the best in the world and permit of relatively low production costs—contributed to the continuance of the development described. These harvests, which in 1955 rose to 646 kilogrammes of fibre per hectare in El Salvador and 610 kilogrammes in Guatemala, are produced without irrigation and thanks to modern machinery and methods as well as to plague control. Central American yields—like Mexico's—are much higher than those of the South American countries (except Peru) and other major producers, such as the United States. (See table 39.)

Cotton planting has had the virtue of awakening the interest of Central American growers in the improvement of farming techniques (the use of modern machinery, selected seed, plague control, fertilization and crop rotation, etc.); this development is helping to form a new generation of agricultural entrepreneurs of a calibre hitherto unknown in the region. Their influence and the methods they use will no doubt spread to the remaining agricultural sectors of Latin America in coming years.

In Brazil the last harvest, which amounted to 405,700 tons, exceeded that of 1954 by only 2.7 per cent, and was similar to the average for the last five years. The

low, and to some extent decreasing, yields per hectare, attributable to the impoverishment of the soil and the consequent repercussions on production costs, perhaps constitute, in conjunction with difficulties arising from competition in the world market, the most serious problems affecting the cotton sector in Brazil. In fact, unit yields in this country are among the lowest in Latin America, together with those of Ecuador, Paraguay and Venezuela. Under these circumstances, the country has had to resort periodically to devaluation of the cruzeiro in order to compete in the world market and at the same time counterbalance the inflationary rise in internal costs. In May 1955, the exchange rate for cotton exports was transferred from the second to the third category,³² which implied that the price paid to producers was substantially higher than in the previous year, despite the fall in world prices. This circumstance, in addition to the planters' desire to offset at least partially the damage caused to the coffee plantations by the August frosts, the fact that large areas formerly used for growing peanuts were abandoned because of the low price for this commodity, and the prospect of an over-all exchange reform, led to a considerable expansion of cotton-planting in the period 1955/56. This is confirmed by the sizeable increase in seed sales by the Department of Agriculture of São Paulo, which reached 1.5 million bags, thus approximately doubling the previous year's volume.

Cotton planting in Peru covered 225,000 hectares, the largest area on record. Although the water supply from most coastal rivers was normal, the weather affected the crop and promoted the onset of plagues and diseases, thereby raising production costs on account of the need to resort to plaguicides. Production (98,900 tons) dropped by 12 per cent in relation to the previous year's, which had been unprecedented. World market fluctuations had a direct effect on the planters' income, since the prices paid to the producer were more than 6 per cent lower than in 1954.

Latin America's cotton exports were larger in 1955 than in 1954, if those of Brazil are excluded. However, it should be recalled that the exceptional exports effected by Brazil in 1954 included a considerable proportion of the surpluses accumulated in 1952 and 1953, and that Latin America was thereby able to reduce the volume of its surplus stocks in 1954/55 from 464,800 to 436,900 tons. (See table 40.)

Except for Nicaragua, Central America was able to place its whole cotton output on the world market without

³² At the close of the year, planters were exerting pressure to have cotton moved to the fourth category.

any great difficulty. Conversely, Mexico was unable to dispose of the whole of its last two crops. The exact size of the surpluses is not known, but they are estimated to have totalled 67,000 and 91,000 tons in 1954 and 1955 respectively. Brazilian exports benefited by the devaluation of the exchange rate for this commodity. At the end of the cotton-trade year (28 February), stocks are calculated to have stood at the same level as in the previous season (45,000 to 50,000 tons) and to have constituted no serious problem.

Peru found little difficulty in selling its exportable production, since mainly long-fibred cotton is produced, which faces less competition on the world market.

To sum up: until the 1954/55 harvest, cotton production had been expanding steadily in those Latin American countries where the crop had been recently introduced and efficient methods of cultivation, resulting in high productivity, had been adopted. The sale of their exportable surpluses had presented no insurmountable difficulties to date, since the price decline had been successfully combated by low costs in countries where production is efficient, and by various protectionist measures in the rest.

At the end of the season, however, a significant change in this situation became apparent. The United States Government announced its new policy for the encouragement of its export trade, and this alone immediately caused a price decline and some unwillingness to pur-

chase fibre on the part of consumer countries. This change in the attitude of the United States is due to the present statistical position of cotton. World availabilities have risen by 30 per cent in the last five years, reaching a level of 11.1 million tons by the beginning of the 1955/56 cotton year. Although demand increased by some 10 per cent during the period in question, world surpluses doubled and by 1 August 1955 they amounted to 4.4 million tons. From 1951/52 to 1955/56 United States surpluses increased from 490,000 to 2.4 million tons, which means that this country now holds 55 per cent of world surpluses instead of only 25 per cent as before. (See table 41.) Among the factors contributing to this situation were the legal provisions which authorized exports only when they were effected at a level not lower than 110 per cent of the support prices paid to planters. Thus United States policy favoured the development of cotton in Latin America by maintaining prices at a relatively steady and profitable level.

Of late, however, United States policy has radically altered, since the decision has now been reached to sell surpluses at competitive prices and on the very easy terms implied by acceptance of payment in the purchasers' national currency and the additional incentive of long-term credits. Under these conditions, the United States has already sold 138,600 tons for delivery during 1956. These sales are a source of direct competition for Brazil, Central America and Mexico, especially as some of them were placed in Latin American countries which were traditional purchasers of the region's own cotton.

7. MEAT

Meat production in Latin America witnessed a marked recovery in 1955 from the slightly declining trend observed during the last five years. A 4 per cent increase over the 1954 output raised it, though by only a small margin, above the peak level of 1950. This change was due mainly to an increment of a little more than 7 per cent in beef production; while in 1954 only 21.6 million head were slaughtered; in 1955 this figure rose to 23.1 million principally as the result of the extraction of far

greater numbers of cattle in Argentina and Mexico. Production of mutton remained practically stationary, since the 16.7 million head slaughtered represented only 176,000 more than in the previous year. Conversely, production of pork decreased by 8 per cent since slaughtering declined by some million head, so that the total was only 11.75 million. This reduction was almost entirely attributable to the sharp falling-off in the slaughtering of pigs in Brazil as a consequence of feed shortages. In the remaining countries, except Chile, production remained stationary or increased slightly. (See table 42.)

^a Including exports of animals on the hoof.

^b Weighted by average unit yields: cattle, 220 kilogrammes; sheep, 18 kilogrammes; pigs, 75 kilogrammes.

The salient feature of meat production in 1955 was undoubtedly the remarkable increase in cattle slaughtering in Argentina, which enabled this country to make great progress in regaining its position as Latin America's leading exporter. Cattle stocks totally recovered from the effects of the drought which had affected this country from 1948 to 1951, and in certain isolated sectors the carrying capacity of pastures was even subjected to some pressure. Consequently, meat supplies for the domestic market became normal, the weekly meatless day being abolished in August, and, moreover, a considerable exportable surplus was obtained. In 1955, 9.5 million head were slaughtered, that is, 16.8 per cent more than in the previous year, when the corresponding figure was 8.13 million. Owing to the substantially higher proportion of calves, cows and heifers in the aggregate number of cattle butchered,³³ meat yields improved by only 13 per cent, totalling 2.05 million tons. Finally, it should be indicated that Argentina's meat production might have been still greater, had it not been for the marketing and, especially, the transport difficulties that prevented the full utilization of the available supply. The inadequacy of the transport system, in particular, caused manifold losses, since breeders were obliged to hold their stocks for much longer periods than would have been required simply to fatten them for market.

The declining trend in beef production in Uruguay became more marked in 1955 as a result of the gradually intensifying competition in recent years, in the first place between crops and livestock, and in the second place between cattle and sheep, for the country's limited natural resources. As an example of the first case, mention should be made of the considerable expansion of the area under wheat, which in the last three years rose from 500,000 to 700,000 hectares, taking up most of the best grazing

lands and particularly the winter pastures. In the second case it should be recalled that owing to the boom in wool prices on the world market, sheep breeding developed to an exceptional extent in Uruguay, so that in 1953-54 sheep stocks were estimated at about 27.5 million head as against 21.6 million in 1946-50 and 18 million during the pre-war period. Conversely, cattle stocks declined from 8.3 million in 1936/40 to 7.9 million in 1953/54. In addition to this unbalanced development of animal stocks, meat consumption, considerable to start with, became the highest in the world. Hence it is easy to understand why Uruguay discontinued its meat exports, which until 1954 contributed a high percentage of the country's aggregate foreign exchange income. The falling-off observed in cattle breeding is largely due to unfavourable marketing and processing conditions which not only hamper the regular delivery of animals for slaughter, but also increase costs.³⁴ The same circumstances have caused the formation of a "parallel" uncontrolled market both for supplying the city of Montevideo and for exports.

In Brazil, although the accelerated growth of cattle stocks seems to have continued—bringing them up to 61.4 million head in 1955 in comparison with 57.6 million in 1954 and an average of only 46.2 million in 1946-50³⁵—production of beef remained stationary, perhaps as a consequence of the strict control of retail prices which was in force during most of the year and was later partially relaxed.

An extensive herd repopulation programme was launched in 1955 in Mexico, where until 1954 foot-and-

³³ In 1954 cows and heifers accounted for only 28.2 per cent of aggregate slaughtering, while in 1955 this proportion rose to 33.6 per cent. For calves, the corresponding percentages were 4.5 and 6.3 per cent, respectively.

³⁴ The existence of cold storage houses with a processing capacity much higher than present production levels (the four cold storage houses of Montevideo can handle 1.7 million head, while only 522,000 were processed in 1955) gives rise to high operation costs which are partly financed through State subsidies and partly involve the payment of lower prices to the producers. Moreover, difficulties in delivering the cattle to the stockyards and delays in payment constitute a serious handicap for stock-breeders.

³⁵ See *Foreign Crops and Markets*, Vol. 72, No. 15, 9 April 1956.

mouth disease and prolonged droughts had prevented the expansion of stocks. The Government created the Fondo de Garantía y Fomento de la Ganadería with capital amounting to 100 million pesos, for the purpose of guaranteeing private credit institutions the recovery of their livestock loans. Two thousand stud bulls were imported from Canada; five national breeding stations were established; 20,000 head of Hereford cattle were distributed, and, with the credit and guarantees provided by the Nacional Financiera, the purchase of 100,000 heifers and 300,000 head of cattle for distribution among farmers was authorized. These measures, together with the opening of the United States border, which encouraged cattle exports, enabled slaughtering to increase by more than 18 per cent.

Finally, Costa Rica, which until 1953 was a net importer of cattle for consumption, became self-sufficient in 1955, thanks to better utilization of its good natural facilities for stockbreeding and to credit programmes and the distribution of zebu stud bulls. In 1955, slaughtering for domestic consumption increased and about 4,000 fat bullocks were exported to countries outside Central America. This raised extraction to a level 2.3 per cent higher than the previous year's and 37.6 per cent above that of 1950.

Production of meat in the remaining countries was normal in 1955.

Latin America's position as a meat exporter improved considerably during the year owing to the substantial increment in both meat and live-weight shipments from Argentina and Mexico.

The increase in cattle slaughtering in Argentina left an exportable surplus³⁶ of about 400,000 tons of carcass meat, which compares favourably with 231,000 tons in 1954 and an average of 284,000 over the five-year period 1950/54. It is also interesting to note the significant change in the composition of these exports, which were shipped mainly to the United Kingdom. When meat rationing ended in July 1954, the population of Britain began to demand increasing quantities of chilled beef instead of the frozen meat they had eaten for so many years. This unquestionably favoured Argentina, since Great Britain's other traditional suppliers—Australia and New Zealand—are too far away to export chilled beef to this market. Thus, while in 1953 and 1954 British imports of chilled meat were only 4,000 and 16,000 tons respectively, in 1955 Argentina exported about 120,000 tons to the United Kingdom.

The eradication of the foot-and-mouth epidemic which broke out in 1953 allowed Mexico to resume its exports of cattle on the hoof to the United States. Sales to this country rose to 243,000 head in 1955, as against only 4,600 in 1954 and 134,600 in 1953.

The decline in Uruguayan meat exports which began some years ago became so acute in 1955 that this country practically disappeared from the world market. In fact, from 61,200 tons in 1951 and 43,900 in 1954, exports of frozen meat dropped to 3,200 tons in 1955. Sales of tinned meat in the same years stood at 12,800, 20,900 and 5,600 tons, respectively.

³⁶ Exports were as follows: 117,300 tons of tinned meat; 158,100 tons of chilled and frozen beef; and 62,300 tons of frozen mutton.

8. WOOL

Latin America's wool clip (greasy basis) reached a volume of 315,400 tons during the season ending 30 September 1955, which was 5 per cent below the level of the previous year and the lowest tonnage recorded in the last five years.

If a comparison is drawn between wool production in Latin America and that of the whole world, it may be seen that the latter has shown a steady improvement in recent years while regional output moved up slowly until 1954 and deteriorated thereafter. (See table 43.) Because the rate of growth was uneven, Latin America's share within the world total, which had reached 17.8 per cent in 1951/52, declined to 15.5 per cent in 1954/55.

Table 43. Latin America: Wool production
(Thousands of tons)^a

Year	World aggregate	Latin America	Share of Latin America within world total (Percentages)
1950/51	1,822.0	323.9	17.7
1951/52	1,836.5	328.2	17.8
1952/53	1,980.5	331.6	16.7
1953/54	2,003.2	332.7	16.6
1954/55	2,030.3	315.4	15.5

Source: Official statistics.

^a Greasy basis.

The fluctuations in the Argentine clip, which accounts for about 60 per cent of the regional aggregate, play a decisive role in the slow evolution of wool production in Latin America. After reaching peak levels of about 200,000 tons from 1948 to 1950, the output of wool started to decline in Argentina, owing to adverse economic conditions, which originated in the low export exchange rate. Hence, in 1955 only 165,000 tons were produced, which is very similar to the clip in 1934/38.

Although production in Uruguay, which ranks second among Latin American producers, declined slightly in 1955 when related to the previous year, it remained at a level of some 90,000 tons, or almost 80 per cent higher than the pre-war level. This development was possible through the remarkable growth of sheep flocks, which have partially displaced cattle from the limited pasture land in Uruguay,³⁷ to the serious detriment of meat production both for domestic consumption and for export.

No significant changes took place during 1955 in the remaining countries, which contribute about 20 per cent of the regional aggregate. It should be noted, however, that southern Brazil has witnessed a phenomenon similar to that of Uruguay, namely, a marked displacement of cattle by sheep as a consequence of high wool prices in the previous year and of the better utilization of grasslands by sheep.

The wool clip in Argentina and Uruguay is mainly destined for export, while elsewhere in Latin America it is in general consumed by local industries. These two

³⁷ While the cattle population decreased from 8.3 million head in 1946-50 to 7.8 million in 1954, sheep flocks grew from 17.9 to 26.6 million head during the same period.

countries rank among the five major exporters of the world, accompanied by Australia, New Zealand and the Union of South Africa.

Wool exports represent a valuable source of foreign exchange for Argentina and Uruguay. During the last five years such exports have accounted for 14 and 43 per cent, respectively, of the total income derived from exports in these two countries.

Argentina's exports, mainly consisting of coarse wool from crossbreeds, rose to 105,000 tons effective weight in 1954/55 (including waste), or 12,000 tons more than from the previous clip. (See table 44.)

^a Greasy basis.

Export prospects for the surplus have benefited, however, from the new exchange measures which were established at the end of 1955 by the Argentine Government, including a rise in the net exchange rate for wool from 6.25 to 12.42 Argentine pesos per dollar.³⁸

The future of wool exports was also favoured by the rising trend in world consumption. In fact, while consumption in the United States had declined steadily in recent years, mainly through the competition from synthetic fibres, an increase of about 4 per cent occurred in 1955, principally because a greater demand existed for garment wool. A significant rise also took place in

³⁸ According to the modifications introduced in the Argentine exchange system, the wool dollar is liquidated at 18 Argentine pesos to the dollar, 25 per cent being retained, which gives a net value of 13.50 pesos to the dollar. At the same time a former 8 per cent tax on sales was reinstated so that the exchange rate is really pegged at 12.42 pesos to the dollar.

the United Kingdom, the world's main wool consumer, where consumption of greasy wool rose from 209,000 to 215,000 tons. In the aggregate, world consumption increased by approximately 3.5 per cent in relation to the previous year.

In marked contrast to Argentina, Uruguay's exports during the 1954/55 wool year declined by 28 per cent in relation to the previous clip and by 60 per cent when compared with 1952/53.

The United Kingdom and the United States, which were formerly the main purchasers of Uruguayan wool, reduced their imports from this source by two-thirds and one-half, respectively, while shipments to Western Germany dropped to less than 50 per cent of the previous year's tonnage. The Netherlands thus ranked as the main customer, by purchasing about 8,600 tons of wool and 6,500 tons of wool tops, which accounted for 25 and 60 per cent, respectively, of Uruguay's aggregate exports during the last clip. A significant event during the year was the export of about 200 tons of wool tops to the Soviet Union.

During the last quarter of 1955, that is, when the new wool year had opened, exports from Uruguay made a sensational recovery and the largest shipments on record were made. In the first six weeks of this new wool year, 30,000 tons of wool and 5,800 of wool tops were registered for export; during the last week of November, 3,000 tons were recorded and in the next two weeks registrations totalled 17,000 tons. This almost exhausted the unsold 52,000 tons held on 1 October. An important factor in this sudden expansion of sales may be that after 1 January 1956³⁹ the export subsidy (established on 15 September to stimulate such exports) was expected to drop from 21 to 14 dollar cents, to remain at a level of 7 cents as from 1 April, and to be eliminated after 1 July 1956.

Prices for wool on the world market, particularly for fine grades, continued to move down during 1955, a movement which became more marked in September when Merino wool was quoted at its lowest price in recent years. In October a slight recovery took place which continued throughout the last quarter of 1955 and early weeks of 1956.

³⁹ This limit was afterwards extended to 31 March.

Chapter IV

INDUSTRY

I. OVER-ALL TRENDS IN PRODUCTION

Latin America's industrial production continued to expand during 1955. The indices showed an increase of 6 per cent in relation to the previous year which, although higher than that recorded during the period 1950-54, revealed a certain weakening when compared with the 7 per cent registered in 1954. (See table 45.)

Table 45. Latin America: Indices of industrial production
(1950 = 100)

^a On the basis of data from the Chilean Development Corporation.

Three factors in particular contributed to the growth of industrial output in 1955: (a) the improvement in demand, as a result of the increased volume of exports, which succeeded in overcoming the effects of the deterioration in the terms of trade and thus favourably influenced domestic demand; (b) the peak level reached by agricultural production, which is a highly important element in determining the income level of the majority of consumers in each country; and (c) the increment in investment, which is estimated at some 3.0 per cent in relation to 1954 for Latin America as a whole, and which had an encouraging effect upon the demand for industrial products.

The development of manufacturing output varied from one country to another, although in almost the whole region it rose above the previous year's level.

In Argentina, where a recovery from the former low levels of activity set in during 1954, production continued to increase progressively during 1955, showing increments of 10 per cent over 1954 and of more than 7 per cent above the figure for 1951, which had represented the previous maximum. This growth was not unconnected with the acute shortage of foreign exchange, which almost excluded the possibility of importing many manufactured articles, and with the increase of over 6 per cent in agricultural production, which raised the demand for such goods. But in 1955, as in other recent years, the growth

of industrial equipment was slow. A persistent weakening in exports of primary products reduced the means required for a steady expansion of productive capacity,¹ especially in the sector of basic industry, which has the greatest influence upon the dynamics of growth. Hence, the increased output in 1954 and 1955 was less the result of an expansion of industry than of a more intensive utilization of installed capacity.

The rate of growth of production weakened in Brazil and from almost 10.8 per cent in 1954 fell to 3.7 per cent in 1955. The prospects of a reform of exchange policy, of changes in the customs tariff and of restrictions on credit all affected output during the final months of the year. But industrial capacity continued to expand, despite difficulties in obtaining foreign exchange and in importing equipment and raw materials. These very difficulties, and the opportunity for high profits from productive activities, make Brazil an attractive field for industrial investment.

The over-all trends which had begun to appear in Mexico's manufacturing industry since the second quarter of 1954 remained unchanged. Industrial output maintained its progressive rate of increase throughout 1955, exceeding the levels of 1954 by almost 10 per cent. Much of this increment was due to the encouraging effect upon the demand for industrial products of the increase in private investment, which is estimated to have surpassed that of the previous year by about 40 per cent. The two consecutive years of substantially higher income in the agricultural sector constituted an additional favourable influence.

Industry in Colombia continued to grow, but at a slower pace than during the period 1950-54. National income did not show as spectacular a rate of increase as in recent years and this was reflected in a relative weakening in demand. On the other hand, imports of those consumer goods which compete with domestic industry expanded in relation to 1954, despite the modifications in foreign exchange policy which were adopted in order to reduce such purchases.

For the first time after a number of years of continued expansion, the volume of industrial production contracted in Chile, and was more than 4 per cent below the 1954 level. Credit restrictions enforced during the final months of the year led to a substantial reduction in sales and ultimately in production. In addition, serious difficulties still hampered imports of machinery and spare parts, raw materials and other elements essential for production, even though more foreign exchange was finally available than had been expected at the beginning of the year.

¹ Machinery replacement has once again been postponed. It is estimated that the replacement of out-of-date equipment by modern machinery would alone represent an investment of more than 350 million dollars.

Industrial output was also lower in Uruguay. The manifest difference between productive capacity and effective production—a characteristic apparent since the early years of the present decade—became even more marked in 1955. As regards supply, competition from imported articles made itself felt, while there was some weakening in demand as a result of the higher cost of living. The expansion of many sectors of Uruguay's industry has exceeded the needs of the limited domestic market and only through exports could full economic utilization of installed equipment be achieved. But high labour costs, unaccompanied by a comparable level of productivity, exclude any possibility of competition on world markets, unless preferential exchange rates are adopted, as in the cases of tanned hides or combed wool tops.

Although protection is limited in Peru, industry developed to some extent during 1955. Nevertheless, problems arising from the policy of a free exchange rate and unrestricted rate have still to be faced. The measures adopted in November 1949 represented a decrease in the purchasing power of most of the population and thus reduced the market available for industry. Moreover, the higher-income groups, who might strengthen the demand for domestic goods, prefer the foreign market, and this is one of the reasons why Peruvian industry has not grown more rapidly during the last few years.

Venezuela was the country with the highest rate of growth for industrial production during 1955. The intensive process of industrialization which began in 1950 did not slacken during 1955; the expansion of plants already installed and the creation of new industries continued unabated.

II. OUTSTANDING EVENTS IN LATIN AMERICA'S INDUSTRY

Although a number of projects and plans were adopted or entered production, those listed below are considered as the most important; it should be noted that they are all in the sector of heavy industry, which indicates that in some countries the distance which separates basic from light industry is being narrowed:

(a) The agreement between the Argentine Government and entrepreneurs and a United States company for the building of a factory at Córdoba to produce motor vehicles. Output will apparently reach 35,000 units annually over the next four years and will contribute to the renewal and expansion of the motor transport park in Argentina.

(b) The establishment of the new plant of the Companhia Brasileira do Alumínio in the State of São Paulo. Initial capacity is for 10,000 tons of aluminium ingot annually, and there are plans for a fivefold increase. Output from this plant will provide Brazilian industry with more abundant supplies of this metal, which is basic for the mechanical and metallurgical sector, and which has hitherto been in short supply owing to import difficulties.

(c) The entry into production of the refinery at Cubatao, in São Paulo State, with a daily capacity of 10,300 cubic metres. In addition to the significance of this plant for the supply of fuels, it will shortly become

the centre of a large petro-chemical industry which will use the residual gases from the refinery as raw material.

(d) The mass production, in São Paulo, of the first diesel engines to be manufactured entirely in Brazil. Although the units produced each month are still few in number, and, furthermore, are single-cylinder models of low horse-power, this is an outstanding event because it indicates the stage of progress reached by Brazil's mechanical industry.

(e) The contract between Chilean capital and a United States company for the manufacture of agricultural tools and equipment. The machinery has already been purchased and the civil-engineering work for the assembly of the plant is at present being concluded. This is a basic industry for Chile, because the articles to be produced—threshers, harvesters, etc.—will play a decisive part in the success of the agricultural programme now under way. In addition, from the metallurgical standpoint, Chile will now begin to mass-produce machines of a high technical level.

(f) The installation in El Salvador, directed by Japanese experts and with a joint capital from El Salvador and Japan, of an up-to-date cotton mill which will have 25,000 spindles and 260 looms.

(g) The increase in the steel-making capacity of Mexico. The production of more than a million tons annually represents an increment of 108 per cent above the 527,000 tons' capacity registered in 1950. The 15.8 per cent annual coefficient of increase is indeed exceptional, and denotes the lines along which Mexico's industry developed during this period.

(h) The inauguration in early 1955 of the first battery of coking plants at Monclova in Mexico which, in addition, to producing some 286,000 tons of metallurgical coke each year, has an annual capacity for 6,600 tons of sulphuric acid, 3,477 of ammonia sulphate, 2,877 of tar products and 12,371 tons of liquid pitch.

(i) The entry into operation of the two works manufacturing railway wagons and diesel engines in Mexico. The former will have an output of 1,200 wagons annually. In addition, a factory for textile-mill machinery is being built, with a capacity for 120,000 spindles and 3,600 looms each year, which will enter production at the end of 1956.

(j) The agreement between an Italian company and capital from Colombia, Peru and Venezuela, to set up a petro-chemical industry in each of these countries. The first objective will be to produce nitrogenous fertilizers (ammonium nitrate, calcium nitrate and urea).

(k) The formation of a company in Peru, with the technical and financial assistance of a Belgian corporation, for the production of explosives, partially on the basis of raw materials to be provided by the petro-chemical industry.

(l) The opening at the beginning of the year of a furfural plant in the Dominican Republic, consuming sugar-cane bagasse as its raw material and with an annual capacity of 9,000 tons which will all be exported to the United States.

(m) The agreement between domestic capital and an Italian company to build a large iron and steel works, at

Puerto Ordaz in Venezuela, with an annual capacity of 150,000 tons of steel ingot. Since Venezuela has the highest per capita steel consumption in Latin America,² the new plant will lead to less dependence upon imports and will give a strong impulse to the development of the mechanical and metallurgical industry.

III. DEVELOPMENT BY SECTORS

The sectors included here represent over 87 per cent of the value of Latin America's industrial output. Their relative importance may be judged from table 46; the rates of growth recorded during the period 1950-55 are shown in figure IX.

1. FOODSTUFFS AND BEVERAGES

This is the most important sector in every country of the region; at the same time it is the most heterogeneous, since it is really composed of a number of dissimilar industries. On the average, foodstuffs account for nearly 75 per cent of the value of production and beverages for about 25 per cent. Particularly significant among the former are mill products, sugar, green coffee, refrigerated meat, rice (cleaning and polishing), preserved foods, edible oils and fats, bakery and confectionery products, and prepared foods. Among the beverages, the more important are liquors, wine, beer and soft drinks.

Except for Argentina, where this sector was affected by the agricultural crisis of 1951-52, and probably Cuba, where sugar production has been declining sharply since 1952, the food-processing and beverage industries have expanded considerably in all countries. This development was particularly pronounced in Peru and Venezuela, where official policy made special efforts to foster it. (See table 47.)

A new increase in production within the region was apparent in 1955; for the seven countries shown in

² It should be noted that this high consumption does not reflect the existence of a large metallurgical and mechanical industry, but rather the high demand for petroleum tubing and structural steel for building.

table 47 it represented an increment of 5 per cent. Commodities showing higher output in relation to 1954 included wheat flour (18 per cent), coffee (7 per cent) and vegetable oils (4.5 per cent). In the case of sugar there was a reduction (3 per cent) because of lower production in Argentina, Cuba and the Dominican Republic.

2. TOBACCO PRODUCTS

With a few notable exceptions, such as Cuba, this is one of the most concentrated industries and, mainly because of monopolies, there are very few establishments in each country. As a rule, the factories are large and are close to centres of production or consumption,³ although there are also establishments which prepare tobacco by hand for smoking or chewing.

Except in Brazil and Venezuela, this industry has grown at a somewhat slow rate in recent years. However, the expansion in Brazil, which is the largest producer in the region, has influenced the figures for Latin America as a whole, which rose by 25 per cent between 1950 and 1955. (See table 48.)

³ All the Latin American countries, from Mexico to Argentina, grow sufficient tobacco to meet at least their own needs. Some specialize in tobacco for export.

3. TEXTILES

As regards the value of production, the capital invested and the man-power employed, the textile industry still ranks second among Latin America's manufacturing activities; yet in the last six years, it has not followed the same dynamic pattern of growth as the other sectors. During the period 1950-55, the volume of production in the manufacturing industry as a whole increased at a rate of 5 per cent annually, while the textile industry expanded by only 2.5 per cent. (See table 50.) This failure to advance as rapidly as other branches of industry had two fundamental causes: (a) already by 1950 production and domestic demand were reaching a certain equilibrium in the main producer countries and only moderate future increases could thus be expected, based on a higher average of *per capita* income and on the vegetative increment in the population; and (b) the pressure of external incentives was weakened by the loss of export markets which had, during the 'forties, maintained a state of unusual prosperity in the cotton sector of some countries.⁴

In 1955, Latin American textile output exceeded the figure for the previous year by 4 per cent; and, although the rate of growth was more hesitant than in 1954, the level of activity may be taken as satisfactory, considering that the latter year was the first of complete recovery. The most active branch in almost all countries was cotton, as consumers showed a preference for cotton goods. Conversely, there was some slackening in the demand for artificial fibres; this was particularly true of piece goods made of filament, since articles made of staple continued to enjoy a good market, thanks to the popularity of fibre mixtures.

Modernization of equipment proceeded very slowly; nor was there any large-scale expansion in most countries, precisely because nearly all of them found it difficult to import equipment. Consequently no significant changes may be expected in the number of spindles or looms. (See table 51.)

⁴ During the war and early post-war years, Brazil and Mexico supplied markets which had previously imported from traditional exporters. When the situation returned to normal, these markets were gradually lost, and Latin American products were able to enter them only as stop-gaps, covering temporary deficiencies in supplies from so-called traditional sources.

4. FOOTWEAR AND CLOTHING

This sector registers a slow rate of growth, although future prospects are good, particularly in those countries where per capita consumption is still extremely low. Expansion will depend less on the vegetative growth of the population than on the raising of the average standard of living in Latin America. Artisan shops predominate in this sector, so that mechanization and productivity indices are low.⁵

From 1950 to 1955, the production index showed no significant changes in the principal Latin American countries as a whole, although (see table 52) there were variations in the output of nearly all of them from one year to another. The majority witnessed some degree of recovery in 1955.⁶

^a Footwear only.

⁵ Furthermore, the equipment in use at many of the larger factories is out of date, and this also affects productivity and quality.

⁶ There were countries where production contracted, Uruguay being a case in point. Footwear factories reduced the volume of output by 15 per cent in relation to 1954, a year in which it had already been low in relation to effective productive capacity. Most of the factories worked 3 or 4 days a week, utilization of equipment barely amounting to 30 per cent.

Footwear manufacture represents from 25 to 75 per cent of the entire sector. The percentage is usually lower in the more advanced countries of the region—Argentina, for instance—because factory-made clothing is more commonly worn there by both the higher and the lower income groups.

Since imports of footwear are very small in nearly all the countries and domestic production therefore meets almost the entire demand, it may be concluded that the consumption of footwear is abnormally low in Latin America. In fact, in only four countries—Argentina, Chile, Cuba and Uruguay—does it exceed one pair of shoes or boots per person annually. (See table 53.) These figures contrast with 3.2 pairs in the United States and 2.7 in the United Kingdom.

^e 1951.

The manufacture of footwear is one of the branches where least progress in quality has been made. This is not only because skill and adequate equipment are lacking, but also because the quality of the leather tends to be poor. There is a broad field for improvement and for technical assistance in this industry, extending from the care of livestock to ensure that hides are not blemished by marks or diseases, to tanning operations and the manufacture of more durable and less expensive shoes.

5. PULP AND PAPER

A glance at indices of production, for the five countries which together produce nearly all Latin America's pulp and almost 90 per cent of its paper, shows that an average annual increase of 5 per cent was achieved in this sector during 1950-55. (See table 54.) Nevertheless, this greater output was insufficient to meet the ever-growing demand for pulp products, particularly that for chemical pulp and newsprint. Of a total of 1.7 million tons of paper and board consumed annually in Latin America, about one million are produced within the region, leaving a deficit—mostly newsprint—of 750,000 tons; in other words, 43 per cent of all consumption must be covered by imports. In the case of pulp, almost 60 per cent of aggregate consumption requirements is at present imported.

This dependence upon imports has made it very difficult to meet demand, partly because of the sharp variations in world prices and available stocks, and partly because of the shortage of foreign exchange which as a general rule has obliged the Latin American countries to limit their imports. Hence the region's paper consumption advances more slowly than would be consistent with the rate of growth of per capita income.

An analysis of the present position of the exporting countries—mainly in North America and Europe—leads to the conclusion that Latin America will not be able to meet the steady expansion of demand through increased imports from traditional suppliers.⁷ As a result, certain Latin American countries have begun to formulate long-range plans for developing their own resources. Some are envisaging production on a national scale only, with a view to meeting their own requirements; in contrast, others—better endowed with fibrous raw materials—are contemplating export possibilities as well.

⁷ See *Pulp and Paper Prospects in Latin America* (E/CN.12/361/Rev.1), United Nations publication, Sales No.: 1955.II.G.4.

Until 1954 the trend in the region's manufacture of pulp products had been characterized by greater expansion in paper than in pulp. However, a change could be noted during 1955, when paper manufacture rose by 8 per cent as against a 10 per cent increase in pulp production. (See table 55.) A number of circumstances were responsible, among which the following are important: (a) many Latin American countries have become almost self-sufficient for grades of paper other than newsprint; (b) the retarded development of regional production of pulp—as well as the difficulties of importing it—has concentrated the attention of industrialists and Governments on the creation of domestic sources for this raw material; and (c) progress in the production of the really scarce commodity—newsprint—has been discouraged by preferential customs tariffs, small margins of profit and, above all, the need for exceptionally heavy investment.

Of the various existing projects for raising pulp and paper production capacity, four will be put into execution during 1956. A new mill will enter production at Puerto Piray in Argentina with a nominal annual capacity of 30,000 tons of pulp for paper and rayon; it is not expected to reach full capacity until 1957 or 1958.

In Brazil the Rio Claro mill will enter production with a capacity of 15,000 tons of bleached pulp for paper and 10,000 tons of pulp for rayon. Eucalypt will be employed as raw material.

Of the two mills which are under construction in Chile in the Concepción area, the newsprint factory—with an annual capacity of 44,000 tons—will begin operations towards the close of 1956, while the second will do so within another year or two, and, according to projects, will produce 47,000 tons of pulp and 10,500 of Kraft. The newsprint mill will not only meet domestic demand, but will provide an exportable surplus.

By the end of 1955 the new plant at Chihuahua in Mexico was approaching completion. It will produce some 24,000 tons of bleached pulp annually, and the same quantity of alpha-cellulose for the manufacture of artificial fibres, cellophane, and extra strong cords for inner-tubes. This will raise the country's total pulp production capacity to some 100,000 tons, which will mean that the entire domestic demand for pulp can shortly be satisfied. Projects for the establishment of newsprint mills to replace imports have also reached an advanced stage.⁸ One of these plants, located in Uruapan, will have an annual capacity of 40,000 tons; the other at Tuxtepec, will produce 32,000 tons yearly.

The principal pulp and paper mill in Peru is installing new machinery which will enable it to expand its present capacity—20,000 tons of paper annually—by 50 per cent. This larger output will be achieved by means of a new procedure thanks to which the cooking time for sugarcane bagasse can be considerably reduced.

The above undertakings account for 22 per cent of the region's current newsprint consumption and 18 per cent of its requirements of other grades of paper and board. These percentages are calculated by comparing output prospects with the figures for consumption. (See table 56.)

⁸ Mexico's imports of newsprint amounted to 45,857 tons in 1955.

6. CHEMICAL AND PHARMACEUTICAL PRODUCTS

The primary chemical industry in Latin America has not developed at the same rate as other sectors. The main obstacle to its progress has probably been the reduced size of domestic markets, which, since current levels of consumption are low, fail to justify the manufacture of a number of its products. Moreover, certain features of the chemical industry, which are less pronounced in the case of other sectors, in the last resort necessitate substantial capital resources. Among such features are the following: (a) the high investment required for the plants; (b) the need to devote funds to research, generally to a greater extent than is required by any other industry; (c) the rapidity with which prod-

ucts and their methods of manufacture change; and (d) the relatively large percentage of out-of-date equipment, which calls for constant modification or renewal.

In its present form, most of Latin America's chemical industry produces articles for direct consumption: pharmaceutical products, paint, soap, matches, etc. A fairly high level of self-sufficiency has been attained for these items and the saturation point is even being approached in some branches.⁹ As a result, the small increments in production are mainly the result of vegetative increases in demand. The industry for raw materials and intermediate products, which should play a basic role in the growth of this sector, is of very little significance as yet.

Many contrasts were to be observed in the sphere of chemicals during 1955. On the one hand, production showed a certain stagnation¹⁰ and, on the other, major projects were prepared and in many cases carried out. Of particular interest is Brazilian investment in plastics—polystyrene, phenolic and vinyl resins—a sector where output is expected to reach 37,000 tons in 1957-58. Petrochemicals constitute another basic industry whose installation was agreed upon, begun or continued in several countries. Brazil, Colombia, Peru and Venezuela will shortly have synthetic ammonia plants, with a combined

⁹ In Brazil, for instance, penicillin production far exceeded demand; strenuous competition among the manufacturers began in 1955, and, to prevent it from intensifying, they agreed to reduce output until such time as they could transform some of their equipment for the production of other antibiotics, particularly streptomycin. Hence in 1955 there was a reduction of almost 10 per cent in Brazil's pharmaceutical output.

¹⁰ In point of fact the 1955 indices show a decline in chemical production. But as the sample on which they were based in each country was small, they have been excluded here as non-representative of the sector. Mexico and Venezuela did not follow the general trend and showed substantial increases.

capacity of 300 tons daily. They will use natural gas and the gases obtained from petroleum refining. Almost all their output will be used to produce nitrogenous fertilizers. Latin America's present production of these synthetic fertilizers will thus be increased sixfold.¹¹ Even though Chilean exports to the above countries amount only to some 90,000 tons, these forecasts once again confirm that the fundamental problem of natural nitrate is one of prices rather than markets; they explain the difficulties of the nitrate industry in face of the competition from synthetic fertilizers.

It is unnecessary to emphasize the importance of these new installations for higher agricultural productivity, since, despite the increase recorded in the use of nitrogenous fertilizers over the last few years,¹² the average consumption figure per hectare for the region (1.7 kilogrammes in 1954) falls far short of crop needs and is much lower than in highly-developed countries.

Apart from fertilizer production, these plants will place their surpluses of ammonia and nitric acid on the market and this will serve as an incentive to the creation of other industries. A Peruvian enterprise, for instance, with the technical and financial assistance of French capital, is to manufacture explosives.

Expansions also took place in the field of other inorganic chemicals, particularly in alkalis¹³ and sulphuric acid. Statistics for total output in 1955 are given in table 57.

Table 57. Latin America: Production of fertilizers, sulphuric acid and caustic soda, 1955

7. RUBBER MANUFACTURES

By contrast with the chemical industry, the manufacture of rubber articles is among the activities where

¹¹ Aggregate output will represent the equivalent of 600,000 tons of natural nitrate.

¹² See table 79 in the *Economic Survey of Latin America, 1954*, *op. cit.*, where consumption figures should be in kilogrammes per 100 hectares and not per hectare as indicated there.

¹³ Of particular importance is the expansion being carried out by the *Planta Colombiana de Soda*, which, after four years of operation, has been obliged to increase output by 50 per cent to meet the growing demand for soda ash.

growth has been most marked during the last few years. Between 1950 and 1955 the index for seven Latin American countries, representing together over 90 per cent of this sector's output in the region, showed an average annual increment of 10.5 per cent, a rate of growth only comparable to that of the steel industry. Although the upswing was apparent in all the countries, it was especially spectacular in Venezuela, where the exceptional average annual rate of 31 per cent was recorded for these years. (See table 58.)

When the expansion of rubber manufactures is analysed, a distinction must be drawn between the so-called "heavy rubber industry", comprising tyre production, and the "light rubber industry", which includes all other manufactures. Tyre output made the major contribution to the increment recorded for the whole sector; production of other rubber goods, although it increased, developed at a much slower rate, perhaps because of competition from plastics, which are replacing some rubber articles.

Some 5.5 million tyres (see table 59) were manufactured in 1955, that is, 8 per cent more than in the pre-

vious year. This greater output was obtained almost entirely through improved utilization of productive capacity, since the new factory in Venezuela entered operation only at the end of 1955, and other expansions carried out during the year will not be reflected in production until 1956.¹⁴

8. CEMENT, GLASS AND CERAMIC PRODUCTS

This sector includes the production of cement, glass, ceramics, bricks, tiles and other items made of clay; most of them are connected with building activities. Because these are basic materials for development, with a large volume per unit of price and relatively easy to manufacture, this sector has depended relatively little upon imports. The indices thus show a fairly sharp rise in recent years, although the extraordinary rate achieved in 1954 appears to have abated somewhat in 1955. (See table 60.) The decline was caused by reduced building activity in Brazil, Chile and Uruguay, and the fact that cement output in Venezuela—the largest branch within the sector in that country—remained constant in relation to 1954, since the rapid expansion of the past five years led the supply in 1955 to exceed the demand. In Argentina, Mexico and, in particular, Peru, production moved upwards, in the last case because of intensive building activity.

Cement and glass are both outstanding branches within the sector; together they represent from 40 to 70 per cent of the total, depending on the country concerned.

The cement industry continued to grow. Production exceeded 11.6 million tons, which represented an incre-

¹⁴ In 1955, Argentina bought more equipment in order to produce tyres for tractors, while Chile began to install new machinery which will provide a 20 per cent increase in present output.

ment of 10.7 per cent in relation to 1954. (See table 61.) Except Uruguay and Venezuela, where very slight increases took place, and in Paraguay, where the level of the preceding year was maintained, all the other countries raised their output in 1955, ranging from 3 per cent in Chile to 54 per cent in Ecuador.

In Brazil, which is the largest producer in Latin America, the cement industry expanded rapidly.¹⁵ Output rose by 9 per cent above the 1954 level and, although a certain equilibrium with demand became apparent during

¹⁵ The Brazilian cement industry included 18 factories in 1954, distributed over 10 states; they employed over 9,000 persons, including office staff, and had 36 kilns in production and 6 under construction or planned. Another 6 plants were being erected, with 8 kilns in all, which should enter production in 1956. Capacity, which stood at 3.03 million tons in 1954, appears to have reached 4.49 millions in 1955.

^a The figures for 1954 have been revised and replace those published in table 74 of the *Economic Survey of Latin America, 1954*, op. cit.

the last months of the year, this industry is still felt to provide an interesting field for fresh investment. Mexico consolidated its position as the second Latin American producer, leaving Argentina, which had followed it closely until 1954, well behind. Although the volume of production rose by 18 per cent, some disparity still existed in Mexico between productive capacity and effective output; in 1955 output represented 79 per cent of capacity. In Argentina, the production increment stood at 9 per cent, and, although 219,000 tons was imported in 1955, it is thought that no shipments from abroad will be required in 1956. In Colombia and Peru the increases amounted to 8 and 13 per cent respectively. By contrast, Venezuela's production, which had almost trebled between 1950 and 1954, remained in 1955 at practically the same levels as the previous year, because supply entirely covered demand.

Latin America's cement consumption in 1955 was estimated at 12.8 million tons, or some 73 kilogrammes *per capita*. This figure is small when compared with 400 kilogrammes in the Benelux countries, 344 in Western Germany and 229 in the United Kingdom. It indicates that, despite the considerable growth in recent years, there is still a very broad margin for expansion in this industry.

The glass industry is composed of some large factories and a great number of artisan-type establishments; the latter encounter serious economic difficulties for the sale of their marginal production on the markets of most countries and cannot compete with the big factories, equipped as they are with automatic machinery to produce phials and containers, bottles, laboratory equipment, glass tubes, light bulbs for incandescent lamps and plate glass. Only artisan production of some artistic merit can evade competition from the machine and thus justify its existence. Most of the modern factories have regular expansion programmes and their growing output has a considerable influence on the indices shown in table 60.

It is in plate-glass manufacture that concentration is most intensive. Because it has a high capital density and can operate economically only when a very large market is available, this type of industry cannot exist in all the countries of the region, and where it does, the number of establishments is very limited. Table 62 shows production of plate glass in selected countries.

9. IRON AND STEEL

Latin America's steel-making production showed increments of 3.5 per cent for pig-iron; 6.4 per cent for steel ingot and 10.2 per cent for rolled products. (See table 63.) The relatively slow rate of growth of pig-iron production was the result of stagnation in Brazil and lower output in Chile. Brazil's production has practically reached maximum capacity and it appears probable that there will be no sizeable increase until the new steel-making furnaces enter production and the expansion programmes for present mills are completed. As for Chile, the relining of the Huachipato blast furnace and a 17-day strike prevented output from exceeding that of 1954.

The increment in Argentina may be attributed to the greater availability of imported raw materials (billet), which permitted a far greater use of installed capacity. In Mexico, the substantial rise in production was largely due to the considerable increase in rolled products, to the more regular operation at the new mills begun in 1954 and to the entry into production of others in 1955. Annual steel-making capacity thus exceeded one million tons, that is, it increased by 108.2 per cent in relation to 1950.

Production at the Paz del Río steel mill in Colombia gradually became normal, after the initial contingencies common to new undertakings. By April 1955, monthly production of ingot had risen from 500 to 4,000 tons and the mill is expected to be operating at full capacity very shortly.

^a Although inaugurated in October 1954, the Paz del Río steel mill actually entered production early in 1955.

Latin America's steel industry also registered major changes in the quality and diversity of its products. Of special significance is the development of the alloy steels required by the transforming industry. Brazil made the greatest progress in this field, not only as to the types of rolled products, but also in forgings and castings, using high and low alloys.¹⁶

Broadly speaking, the level of steel consumption remained above production, but no shortage existed, since any deficit was met by imports, which in some countries even exceeded the demand. This was so in Brazil, where, despite growing domestic output, 322,000 tons of steel were imported in 1954, or 100,000 tons more than the average for previous years. Another 200,000 tons were imported during the first six months of 1955. These large shipments affected domestic production and, for the first time in its history, Volta Redonda closed the year with accumulated stocks.¹⁷ Also for the first time, Brazil began to export steel products to industrialized countries. During 1955, some 20,000 tons of pig-iron were shipped to the United Kingdom and at the beginning of 1956 preparations were being made to send a similar tonnage to the United States.

Latin American plans for the development of steel making have proceeded. Work continued on the San Nicolas expansion projects in Argentina.¹⁸ The Companhia Siderurgica Nacional of Brazil was granted a loan of 35 million dollars to help in the enlargement of the third blast furnace at Volta Redonda and to purchase the equipment required to complete the original plan for attaining a million tons of rolled products annually.¹⁹ Meanwhile other enterprises continued the building of further installations, especially in São Paulo and Minas Gerais, aimed at creating productive capacity in good time to meet future short-term demand, mainly from the motor vehicle industry.²⁰ One of the important projects on the verge of implementation is the new integrated steel mill to be located at Santos, on the coast of the State of São Paulo. Its initial capacity will be slightly over 200,000 tons of broad sheet yearly; it will later rise to 600,000 tons, when projected expansions have been made.²¹ This mill will be outstanding both because it is the first of its kind to be located on the coast and because the production programme includes a predominance of products utilized by domestic transforming industries, all of which were formerly imported. Expansion proceeded actively in Mexico, particularly in the centres of Monclova and Monterrey, where additions to existing capacity will comprise a cold rolling mill of 56,000 tons, a semi-continuous combination rolling mill of 120,000 tons, three electric furnaces for 245,000 tons and an electro-

lytic installation for 45,000 tons a year of tinplate, which will permit a 50 per cent saving in tin consumption. The installation of the Chimbote rolling mills in Peru was practically completed, and the first consignments of imported billet were expected to arrive early in 1956 so that the rolling mills will be able to operate while the two electric furnaces for steel ingot are being assembled. Venezuela, in turn, signed a contract with an Italian firm for the establishment of a steel mill at Puerto Ordaz. It will have an annual capacity of 150,000 tons of ingot and the date of completion has been fixed for the end of 1957. All these new undertakings, together with the efforts of some countries to diversify their steel production, are clear indications that Latin America is entering upon a stage of definite expansion in this important basic industry.

10. TRANSFORMING INDUSTRY FOR IRON AND OTHER METALS

This is one of the sectors which most strongly influence the dynamics of a country's economic development, because it comprises the mechanical and metallurgical industries manufacturing equipment for agriculture, industry, mining, transport and energy, all of which are essential for increasing production and raising productivity.

Among the countries where this sector has developed rapidly during recent years is Brazil. Domestic production has already replaced almost all imports of durable consumer goods²²—metal furniture, electrical household appliances, radiotelephone equipment, etc.—and the present aim is to produce building equipment for heavy industry.²³ For this purpose, the Associação Brasileira para o Desenvolvimento de Industria de Base has been created. Through its members—the principal Brazilian enterprises in this field—the Association has begun to lend its services to the petroleum industry²⁴ and the heavy chemical industry.²⁵ The establishment in Brazil of two important European enterprises will considerably accelerate activity in these branches of the heavy mechanical industry.

The manufacture of parts or spares for motor vehicles has developed rapidly in Brazil and some exports are now being made. For some two years, Brazilian industry has supplied 30 per cent of the weight of all vehicles; in

¹⁶ When special steels are taken to include such items as rolled products for machinery and tools, sheet for motors and transformers and spring steel, Brazil's consumption in 1955 was about 80,000 tons, of which 60 per cent was supplied by domestic production.

¹⁷ The only item in short supply was that of heavy bars, which are not yet produced in Brazil.

¹⁸ A major step towards the accomplishment of this project was the approval of a loan of 60 million dollars, early in 1956.

¹⁹ This development will right the balance between Volta Redonda's production of pig-iron and of rolled products.

²⁰ The annual manufacture of 50,000 medium-sized lorries will alone represent an additional consumption of 20,000 tons of special steels, or some 40 per cent of the output registered in 1955.

²¹ The Brazilian authorities have announced a target of 2 million tons of ingot by 1960.

²² In certain branches, such as the manufacture of table and wall clocks, productive capacity exceeds consumer needs and the industry is currently facing certain difficulties which it is trying to alleviate or overcome through exports. It is also estimated that the present rate of production of sewing machines—156,000 units in 1954 and 224,000 in 1955—will within two years exceed domestic market requirements and that an export policy must be planned immediately.

²³ The industry manufacturing machinery and equipment had idle productive capacity between 1946 and 1953 because it could not compete with imports, which enjoyed preferential treatment. Since 1954, as a result of import difficulties, this branch has displayed great activity. Moreover, since imported machine tools were relatively cheap in terms of cruzeiros, mechanical and metallurgical undertakings tended to add equipment to their installations, without considering how intensively it could be utilized. This situation has now changed, and because of the high cost of machinery, the companies are attempting to make the best possible use of their productive capacity.

²⁴ Some 60 per cent of the equipment for the Mataripe refinery which will have a capacity of 35,000 barrels a day, is to be produced domestically.

²⁵ All the equipment and materials for a freon gas factory now being installed have been produced in Brazil.

certain enterprises this figure amounts to 36 per cent and it is hoped to exceed 48 per cent in 1956. There is every indication that by 1959 domestic industry will produce 88 per cent of the weight of the motor vehicles required by the country at that time. The remaining 12 per cent, consisting of more complicated machinery, will still be imported. In 1955, several large enterprises planned to install or expand their factories, and are only awaiting favourable official decisions as regards import policy.

Great activity in this sector was also recorded elsewhere, although the rate of development was not so rapid as in Brazil. Agreement was reached in Argentina between the State, local entrepreneurs and a United States company for the manufacture of motor vehicles. The factory is being built at Córdoba and the installation work is fairly well advanced. Moreover there are plans to manufacture agricultural implements, electric motors for various uses, stationary diesel engines, pistons and piston rings, office machines, etc., which will increase and diversify the present output of Argentina's mechanical industry. In Mexico, the production and assembly of equipment, machinery, motors and vehicles, has received strong encouragement since 1954, when the exchange rate was modified. The higher tariffs on some units pro-

duced and assembled abroad, as well as the increase in their prices in terms of national currency, have reduced imports, shifting demand to domestic products at the new market prices. This incentive has affected iron and steel production and major changes have thus come about in the volume, the quality and the diversity of the materials required by the mechanical industry. A measure of the considerable development in several branches of the sector which also took place in Chile is the inability of the Huachipato mill to meet simultaneously both domestic requirements²⁶ and external commitments, which are now fairly small. Progress was particularly marked in the output of electrical household appliances, which is now satisfying a high proportion of consumer demand. A very significant step—which may be considered as the major event in Chilean industry during 1955—was the establishment of the first large factory for agricultural machinery. The results of these efforts on the part of private domestic capital and of foreign capital and techniques will very soon be apparent in the yields and productivity of Chile's agricultural sector.

²⁶ The domestic Chilean market for certain steel products fluctuates considerably, so that delivery dates cannot always be punctually met by the producing company.

Chapter V

MINING

1. RECENT EVENTS AND TRENDS

During 1955 the major mineral industries in Latin America continued, broadly speaking, to follow the trends which had been established in previous years.¹ Although production remains predominantly for export, the very low percentage of output which is consumed within the region has shown a persistent tendency to rise. Nevertheless, the proportion is so small that Latin America's mining industry continues to be mainly dependent upon demand in markets outside the region. The prices of a number of the major minerals are subject to short-term fluctuations and in few other productive sectors do price variations have a more effective and rapid influence. The price problem cannot therefore be divorced from any consideration of the mining situation in the region.

Regional production of tin dropped for the third successive year. The future of the tin mining industry in Latin America was complicated by the following uncertainties: (a) the policy of the United States Government with regard to the Longhorn (Texas) smelter, which remained in operation throughout 1955; (b) the future stockpile needs of the United States Government; (c) the International Tin Agreement, which has now been ratified by a sufficient number of governments and will probably become effective during 1956; (d) the extent to which the level of world economic activity during 1955 will be maintained.

Production of copper, lead and zinc continued to rise as a result of unprecedented peacetime demand by consumers in Europe and the United States. Output of zinc in Latin America surpassed the peak achieved in 1954 by about 16 per cent. Regional production of copper increased by more than 12 per cent, exceeding the post-war record set in 1952, even though work stoppages due to labour disputes kept production from rising to capacity levels during several weeks of the year. New investment in copper mining and ore-dressing plants in Latin America and elsewhere should result in an annual expansion of output for the next eight or nine years.

The relation between the Latin American production of iron ore, bauxite and sulphur, and world levels of industrial activity is more complex. Exploitation of Latin American deposits of these minerals results from long-range development programmes on the part of the major consumers. Plans for utilizing Venezuelan iron ore, for example, were developed by integrated steel producers before the Second World War. Expansion programmes for bauxite and sulphur production facilities have been planned and executed in a similar manner and they would probably have been put into effect regardless of business-cycle conditions. As the use of these commodi-

ties is determined largely by technical considerations, Latin American production of bauxite and iron ore was not noticeably affected by the mild recession in the United States during 1953-54.

2. COPPER

During 1955, the favourable influence of the business cycle was nowhere more apparent than in the world copper market. This was not abnormal, since more than half of the copper in highly-industrialized countries is used for construction, electrical and communications equipment, machine tools and other heavy industrial components, whose output plays a leading role in economic cycles. During 1954 and 1955, industrial production in both Western Europe and the United States registered one of the most rapid peace-time advances in history.² The impact of these events can be observed in figure X which shows the world consumption of copper by areas since 1947. A relatively large rise was registered in Europe during 1954 and in North America during 1955.

A second factor affecting the copper market since mid-1954 has been the large consumption increase in the under-developed nations of the world, and especially in the centrally-planned economies of Europe and Asia. Consumption in the latter group of countries, excluding their domestic output, has taken the following forms: (a) direct shipments of refined and unrefined copper from producers and re-exports from other countries; (b) imports of fabricated copper products and of machinery and equipment containing copper and copper alloys.

A partial measure of the increase in these latter categories during 1954 and 1955 is provided by the data in table 64. It should be emphasized that these statistics are limited to exports from Western Europe of refined and unrefined copper in bars and of simple fabricated products (uninsulated wire and cable, rods, pipe, etc.). No estimates are made of the volume of copper incorporated in electrical equipment and other manufactured products exported to the centrally-planned economies.³

The movements of copper prices and production over the past five years are shown in figure XI. Noticeable increments in world production occurred in 1952 and 1955, the years when prices also increased. It is apparent

¹ See Chapter VI, Energy, for a discussion of coal and petroleum.

² In Western Europe, "the 10 per cent increase in industrial production between 1953 and 1954 was practically repeated between 1954 and 1955". See the *Economic Survey of Europe in 1955*, United Nations publication, Sales No.: 1956.II.E.2, p. 1. A seasonally adjusted index of industrial production for the United States stood at 144 in December 1955, as compared with 130 a year earlier and 123 in July 1954 (1947-49 = 100).

³ London commercial circles estimate that total copper imports into the Soviet Union during 1955 stood around 100,000 tons. It is apparent from table 64 that this relatively large figure has been attained since the middle of 1954.

^a Fabricated products (group 682 of the Standard International Trade Classification), excluding forgings and castings.

that the difference between prices in London and New York, which had diminished during 1954, widened during the first quarter of 1955. This had the effect of diverting a high proportion of Latin American exports during 1955 from the United States to European markets

(especially the United Kingdom). However, demand increased steadily in the United States, partly because consumers required to replace inventories which had been reduced during 1954. Copper producers responded during the first quarter of 1955 by raising the price of the

metal sold on the New York market to 36 dollar cents per pound.

The shortage was aggravated by prolonged strikes at plants and mines in Northern Rhodesia, Chile and the United States, which reduced the supply of copper by approximately 131,000 tons. For the greater part of the year, the United States Department of Commerce imposed export quotas on copper and copper-base alloy scrap, wire, cable and refined copper. In the United Kingdom, 66,000 tons of primary copper were released from stockpiles to relieve the shortage. Between 16 October 1954 and 30 September 1955, more than 65,000 tons had been diverted from the United States strategic stockpile or released from other inventories accumulated by the Government of that country. A new equilibrium was finally sought in September 1955 at 43 dollar cents.⁴ At this price, the demand for copper continued at a high level into 1956.

The two-cent tariff on copper in the United States, which had been negotiated with the other contracting parties to GATT in 1947, had been suspended until

30 June 1955. Provision is made that if the price drops below 24 dollar cents a pound, delivered Connecticut Valley, the suspension will be revoked. Since this price was exceeded throughout the year, the tariff was not put into effect in 1955.

Parallel with the increase in world production mentioned above, output of copper in Latin America was higher in 1955 than during any year since 1948. Production in Chile and Peru rose by 45,900 and 4,200 tons, respectively (see table 65). The new Chilean copper law, which came into force in May 1955, led to an immediate lowering of the taxes paid by the large mining companies and placed primary emphasis on profit taxes. In addition to a basic tax of 50 per cent on profits, the law imposes a surtax which diminishes from 25 per cent to zero as output increases to 600,000 tons a year. The law also restores to the companies the control over sales previously exercised by the Central Bank. Since the date of enactment, investment projects announced by the large mining companies have totalled 226 million dollars, which is the largest investment programme ever undertaken by the industry in Chile.

The world's capacity for copper production is also rising rapidly. Table 66 shows the copper output in 1955 of the mines which have expansion programmes in progress and indicates how their annual capacities and those of new properties scheduled to enter operation are expected to rise during the period ending in 1958. These estimates were made on the basis of announced expansion plans. Other projects may be forthcoming if demand for copper continues at its present high level. It is estimated that world capacity will exceed 2.9 million tons in 1958, apart from the capacity of the centrally-planned economies. (See table 66.)

The slight decline in projected Latin American production indicated in table 66 reflects the anticipated depletion of one deposit in Cuba. However, production in the region is expected to rise in 1959 when the Toquepala mine in Peru enters operation with a scheduled

capacity of 120 thousand tons. Further expansion is anticipated in 1961-62 when the El Salvador (Indio Muerto) project in Chile comes into production with an eventual capacity of 100 thousand tons.

As indicated above, the influence of long-term factors has been obscured in recent years by very pronounced cyclical fluctuations in the short-term determinants of the demand for copper. The data presented in figure X demonstrate that no real growth trend has been apparent in the North American market since the Second World War. As pointed out in an earlier edition of the *Survey*,⁵ a declining trend in the relationship between industrial output and copper consumption in the industrialized countries can be observed during recent years. In other words, copper consumption in the United States and in the major countries of Western Europe since 1949 has undergone smaller proportional changes than industrial

⁴ In February 1956 the New York price again rose to 46 dollar cents.

⁵ See the *Economic Survey of Latin America*, 1953, *op. cit.*, pp. 180-181.

output, in relation to the years 1947-49 and earlier periods. This is attributable to the fact that the copper industry faces competition from several metals which have made inroads into the consumption pattern during the post-war period.

^a Excludes the Eastern European Republics, the Soviet Union, Mainland China and North Korea.

^b Refers to Australia, Austria, Israel, Norway and the Philippines.

Aluminium wire with a steel core has displaced copper for long-distance transmission lines, a change which appears permanent. Other typical substitutions of aluminium for copper are fractional horsepower motor windings and light-bulb bases. There has also been an accelerated shift to the use of steel instead of brass in shell cases. Technology has furthered the process of replacement by the introduction of the numerous clad metals, which use proportionately less copper. Printed electrical circuits have also entered some fields as a substitute for copper wire, while aluminium and stainless steels have reduced the use of copper in the building industry.

Copper has retained certain markets in the past because aluminium has been in short supply. In addition, numerous industrial uses remain for which copper is particularly well suited. A concentrated effort to produce a durable radiator for motor vehicles of a material other than copper has not yet yielded results. The heating, air-conditioning and refrigeration industries, in which copper tubing is used extensively and is unexcelled, will probably continue to absorb substantial tonnages of this metal.⁶ However, the long-term growth trend has been decidedly less favourable for copper than for most of its potential substitutes.

3. TIN

Increased world consumption of tin during 1955 tended to bring supply and demand into better balance than during the two preceding years. A relatively minor decline in estimated world production during 1955 resulted from a three per cent reduction in Bolivian exports of tin concentrates. In 1953, world production had exceeded consumption by 44,200 tons; in 1954, by 37,100; and in 1955, by 27,300 tons (see table 67). An increase

of approximately 6.4 per cent in world consumption of primary tin resulted in a sharp depletion of consumer stocks by the end of 1955.

Minor changes in market conditions therefore had the effect of causing wide fluctuations in tin prices. In December 1955, the New York market temporarily reached 1.10 dollars per pound, as compared with the lowest level of 0.86 cents per pound registered during January of the same year.⁷ Although the price tended to rise during 1955, the volume of tin entering the strategic stockpile maintained by the United States Government was almost equal to the difference between world production and consumption. The minimum stockpile objective for tin was reached some time ago and the long-term objective should be attained by June 1956. With the complete termination of official Government stockpile purchases in the United States, a sizeable surplus may appear during 1956.

The International Tin Agreement, 1953, provides for the establishment of an International Tin Council with powers to determine from time to time the quantities of tin which may enter world trade through the imposition of export quotas. By February 1956, the Agreement had been ratified by national parliaments on behalf of the following producers: Belgian Congo and Ruanda-Urundi, Bolivia, Federation of Malaya, Nigeria and Indonesia, for a total of 934 votes. The following consumer governments have also ratified the Agreement: Australia, Belgium, Canada, Denmark, Ecuador, France, India, the Netherlands and the United Kingdom, for a total of 347 votes.⁸

⁷ However, by 16 February 1956, the New York price had fallen just below 1.00 dollar per pound. The causes of this temporary price increase, *inter alia*, were: (a) uncertainty over the future supply owing to political disturbances in Malaya and the Near East, and (b) heavy buying to build up inventories at the end of the year.

⁸ The Agreement was to have entered into force when ratified by producing countries holding not less than 900 votes and at least nine consuming countries holding not less than a total of 333 votes. The United States has indicated that it will not adhere to the Agreement. In addition, Brazil, Switzerland and Western Germany have not signed it to date.

⁶ United States Bureau of Mines, *Mineral Facts and Problems*, Bulletin 556, March 1956.

The actual date of entry into force is to be fixed by the ratifying Governments. The Agreement aims at stabilizing market conditions through the establishment of a buffer stock up to the equivalent of 25,000 long tons of tin metal.⁹

If the International Tin Agreement becomes effective in 1956, the contributions to this buffer stock should offset the effects on the world market of a possible termination of strategic purchases in the United States. In the absence of a prolonged world depression, the long-range demand prospects for tin appear to be promising. As a result of extensive research in recent years, new uses for tin are being developed to replace at least some of the losses in former applications. The most important of such developments is the coating of various products with tin-base alloys by electro-deposition; a still growing field for tin salts is in the preparation of electrolytes for use in this process.

The United States Government is faced with the problem of the management and eventual disposal of the Longhorn (Texas) tin smelter. Costs are higher at this smelter than elsewhere, largely because it accepts all grades of concentrates, some of which are very costly to treat. In 1955, a resolution was passed by the United States Congress, permitting the smelter to be operated until 30 June 1956. This resolution also requests the Executive to study and present to Congress its recommendations as to the most feasible method of maintaining a permanent domestic tin smelting industry, under public or private ownership. The final decision as to the operation or disposal of the Longhorn smelter will be subject to approval by Congress.

Excluding the Longhorn plant, adequate smelter capacity exists today to meet world requirements for tin consumption. Since no single country controls either the ore production or the major smelters, there will be continuing competition among the smelters for the ores and among the producers for world markets. In this connexion, an important British firm has contracted to purchase 50 per cent of the Bolivian tin ore produced over a period of five years dating from January 1956.

The Longhorn smelter currently absorbs about half of Bolivia's output of tin concentrates; if it were closed they would have to be sold to European smelters. It is doubtful whether as high a price could be received on the open market for Bolivian concentrates, since operations at the Longhorn smelter have shown a consistent loss. But it would be difficult to estimate the price-differential represented by this loss, since demand conditions for tin metal are likely to vary over the next few months. Moreover, some proportion of the tin metal produced by the Longhorn smelter has been of a type which cannot readily be sold for use in tin plate.

⁹ Initial contributions to the buffer stock are to be made on such a date as the Council may decide. Producing countries will make initial contributions equivalent in the aggregate to 15,000 long tons of tin metal, 25 per cent of which must be in cash. Percentage contributions of tin metal and cash are allocated among producer countries as follows: Belgian Congo and Ruanda-Urundi, 8.72; Bolivia, 21.50; Malaya, 36.61; Nigeria, 5.38; Indonesia, 21.50; Thailand, 6.29 (article VIII, sections 1 and 2). "Cash" is defined in the Agreement as United States dollars or pounds sterling.

4. LEAD AND ZINC

The expansion of demand for zinc alloy die castings and lead-base battery plates in the United States to meet the requirements of the "eight million" automobile year was perhaps the outstanding feature of the world market for lead and zinc. Demand in Europe also attained record levels. Aggregate world consumption of lead is estimated to have increased by about 5 per cent and that of zinc by 12 per cent.¹⁰

World production of lead rose by 2 per cent above 1954 levels. In marked contrast to the situation for copper, tin and zinc, and despite a sharp depletion of smelter stocks, the world lead market remained calm throughout the year. Prices rose by one dollar cent per pound to sixteen cents during the last two quarters. However, the total world supply, including recoveries of secondary lead, currently exceeds requirements. Regional production has shown a slight downward trend since 1952. (See table 68.)

North American consumption of lead expanded significantly in the building and ceramic industries, and in the fabrication of nuclear shielding materials.¹¹ This latter application should grow with the increasing production of atomic power and use of radioisotopes. There has been no definite trend in regional consumption over the last five years.

In 1955, world production of zinc rose by some 8 per cent (see table 69). As noted earlier, output in Latin America attained a level about 16 per cent above that of the previous year, continuing a trend which has been apparent since 1951. The increment in 1955 was particularly marked in Argentina, Guatemala and Mexico.

Zinc prices rose rapidly during 1955, although in the second half of the year there was a drop in deliveries to the United States Government, which reached the lowest level since the accelerated stockpiling programme went into effect. Advances on the New York market were registered in the second and third quarters of 1955.¹² The over-all expansion of demand for zinc has shown a steady upward trend, resulting in higher prices and greater production. Although this demand has shown instability in the past, the present trend is supported in part by the stockpiling policy of the United States. Despite some criticism, the objective of an expanded stockpiling programme has been followed since mid-1954 as an alternative to increases in the tariff on this metal.

5. IRON ORE

The upswing in the regional production of iron ore during 1955 exceeded the annual rate of increase registered during the years 1951-54. This greater output took place despite reduced production in Brazil and Chile, and arose largely from the continued expansion in Venezuela at Cerro Bolivar and, to a lesser extent, at the El Pao mines. Two more large concessions, as well as others

¹⁰ Discussion by Mr. Simon D. Strauss before the National Industrial Conference Board, as reported in *Metal and Mineral Markets*, New York, 26 January 1956.

¹¹ These uses are not reported separately in consumption statistics. See "Lead Survey and Outlook", *Engineering and Mining Journal*, New York, February 1956.

¹² In February 1956 the price stood at 13.5 dollar cents as compared with 11.5 in January 1955.

held in reserve by the Government of Venezuela, were not exploited during 1955. Production from the Marcona deposits in Peru has continued its rapid increase. (See table 70.)

The significant drop in Chilean production, which caused the country to move from third to fourth place in regional iron ore output, was perhaps due to the exhaustion of good ore at the El Tofo mine. Port facilities at Guayaacán, which will serve the new El Romeral mine after El Tofo has been exhausted, were completed in 1955. During the year the Cerro Negro and Carmen deposits of high-grade iron ore, in the Atacama area, were under development. The mineral is to be shipped to

the United States and Western Germany for mixing with lower-grade ores. The iron ore production of the small and medium mining companies in Chile increased by 272 per cent during 1955, rising from 169,000 to 632,000 tons.

In the same year, a large iron ore producer in Brazil received a loan of almost 34 million dollars from the Export-Import Bank with which to buy mining and railway equipment. It is thought that these developments will raise production in the State of Minas Gerais from 2,262,000 to 3 million tons annually.

As North American steel producers expect to add 16 million tons over the next three years to their present

productive capacity of 128 million tons, their iron-ore requirements will continue to grow at a rapid rate. In addition, the current tendency toward producing more pig iron in each blast furnace necessitates the use of ores with a higher iron content than those formerly consumed. This will doubtless encourage greater output of the high-grade Latin American product, in view of the current high cost of concentrating the lower-grade materials.

Although no statistics for 1955 are yet available, there has been a steady upward movement in regional consumption. An important new consumer is the steel mill at Paz del Río, Colombia, which entered production in 1955. The discovery of additional deposits of iron ore in the Paz del Río area was announced in the same year. The existence of these new resources means that the supply of iron ore for the steel mill will be sufficient for about 50 years, at a rate of exploitation of 3,175 tons per day, or about three times the current rate.

6. BAUXITE

As a result of expansion programmes undertaken since 1950, the alumina capacity of North America has been doubled, thus increasing dependency upon imported bauxite. In addition to the supplies for alumina, from which virgin aluminium is made by the Hall process, bauxite requirements for abrasive, chemical, refractory and other uses have increased. As a result of the higher demand, existing production facilities in Latin America have been expanded and new resources are being developed. Large producers of aluminium are exploiting deposits in British Guiana, the Dominican Republic, Haiti, Jamaica and Surinam. Regional production of alumina is confined to Brazil and Jamaica. Data on regional production and consumption of bauxite are presented in table 71.

Expansion programmes had been completed in all these areas—with the exception of Brazil, Haiti and the Dominican Republic—and were in commercial operation during 1955. In Brazil, construction began in the course of the year on an integrated primary aluminium plant, which will include a section for producing alumina. The plant will be located at Rodovalho, 75 kilometres from São Paulo, and will produce roughly 30,000 tons of alumina per year from domestic bauxite.

The mining installations on the Plateau de Rochelois, near Sainte Croix in Haiti, are nearing completion, although no exports of ore have yet been made. Experimental shipments of ore have begun from the mine at Pedernales in the Dominican Republic, which is expected to enter commercial production during 1956. Reserves recently explored in Haiti and the Dominican Republic represent not less than 30 million tons of bauxite, averaging 47 per cent alumina.¹³ Bauxite resources of the major producers in Latin America were recently estimated to total 656.6 million tons, or almost 41 per cent of known world reserves. (See table 72.)

7. SULPHUR

Native sulphur, pyrites and other metallic sulphide ores, petroleum gases, coal, gypsum and various industrial wastes all contributed to the world supply of sulphur. The present structure of the world industry is, however, based on the price and availability of sulphur produced by the Frasch process, which has radically modified the previous pattern of supply.

As late as 1952, Latin America was still a net importer of sulphur.¹⁴ But the region has now become an

important source of world supply with the exploitation of the salt dome area of the Isthmus of Tehuantepec in Mexico by means of the Frasch process. (See the production data in table 73.) Since mid-1954, when production

in the Tehuantepec area began, the monthly figures for Mexico's output have risen rapidly and in 1955 the volume attained was 520,800 tons as compared with 115,100 in 1954. Exports from Mexico in 1955 amounted to only 180,000 tons owing to transport difficulties and the need for building up stocks. Installations at the port of Coatzacoalcos are at present being enlarged to handle the greater volume of production and will materially assist increased sulphur shipments abroad.

The rapid advance of production in Mexico has been the only major change in the region's output of native sulphur. (See again table 73.) Production in Argentina has moved up steadily, reaching a peak figure of 22,000 tons in 1955, but imports still account for a major share of consumption. Chilean output has been uneven and is principally hindered by high operating costs. Elsewhere there have been no significant changes, partly because the price for sulphur imports remains relatively low. A considerable problem exists in Brazil, where imports continue to rise and no native sulphur deposits have been found.

Chapter VI

ENERGY

1. INTRODUCTION

During 1955 gross energy consumption in Latin America increased by 6 per cent. Although this represents a 4 per cent increment in *per capita* consumption, there was no major expansion of the region's energy resources in relation to the gross product, since the latter rose in the same proportion.

The consumption pattern presented the same general features observed in the post-war period, namely, a steady, rapid increase in the use of electric energy and a gradual displacement of mineral coal and vegetable fuels by petroleum derivatives. This latter development was reflected in the tendency of demand for coal to remain stationary, while the consumption of vegetable fuels showed a slight decline.

In the aggregate, the level of electric energy production rose considerably during 1955 as compared with the preceding period. However, the increases were insufficient to eliminate all the existing shortages, although the supply improved in many areas where it had previously been inadequate. Because of the rapid growth of demand, a deterioration is to be feared in the next few years, unless new and greater efforts are made to expand the installed capacity of electric power plants.

There was a substantial increment in Latin America's output of refined petroleum, particularly in Mexico and Venezuela. Crude oil extraction in the other countries expanded to a smaller degree, although the percentage increase was high in some cases. Because of the pressure exerted by the growing demand for derivatives, several importing countries were obliged to use a large share of their exchange resources for fuels. To reduce the incidence of such imports upon the balance of payments, these countries had to expand their production of crude oil and their refining capacity. For Latin America as a whole, refining capacity rose by 14 per cent in 1955.

In certain countries transport problems which were hindering or actually preventing production at given oil fields have been solved by building pipelines, but greater efforts in this direction are still required to remove all the obstacles.

The deficit in the electricity supply and the ever-increasing foreign exchange expenditure on fuel imports constitute such serious problems that they have led several Latin American countries to accelerate the preparation and implementation of development programmes and plans for the energy sector. Broadly speaking, such plans cover only some aspects of the problem, such as the electricity supply or various phases in the production of petroleum. The more complete projects are those relating to the development of electricity production, but their execution tends to be retarded by financial, ad-

ministrative or technical difficulties, which also affect fuels.

Great importance is attached to increasing energy supplies, and to this end the official organizations responsible for developing production of every type of energy have been more active and new specialized institutions have been created. Such a policy does not imply that this sector of the economy is reserved for State action alone, since parallel measures have been adopted which aim at encouraging private capital to play a larger part. Some countries have conceded new areas to private petroleum enterprises or have sought their co-operation in other aspects of the industry; elsewhere new legislation to authorize this type of operation is under consideration. There is also an obvious trend towards making electricity enterprises more profitable, which would render this field more attractive to private investment and would facilitate capital formation in government undertakings.

The substantial investment channelled towards this sector reflects the magnitude of the financing problem. In 1955, it represented 12 per cent of aggregate Latin American investment and 9 per cent if only the share earmarked for the supply of the region itself is taken into account. Moreover, 20 per cent of all public investments was used for energy. But the maintenance of a high rate of economic, industrial and urban development over the next few years will require a sustained and co-ordinated effort, at the technical and administrative levels as well as in domestic and external financial planning.

2. THE PATTERN OF CONSUMPTION

Although Latin America's total energy consumption rose by 6 per cent in 1955, the expansion did no more than keep pace with that of the gross product in the same year, and signified no great increase in energy resources. The rate of growth varied considerably from one country to another, but the reasons were different in each case. Nevertheless, there is no doubt that very intensive efforts were made—some countries even had to import a growing percentage of their domestic consumption requirements—in order to raise energy supplies to the level of demand. But such endeavours to expand the sources of energy supply may be insufficient for the future maintenance of a high level of economic activity in many of those Latin American countries where setbacks are already holding up the putting of new projects into effect. In the region as a whole, aggregate gross and per capita energy consumption rose in 1955 at a rate similar to that of 1954; in other words, the rate observed in the immediate post-war years was recovered, after some slackening in 1952-53. (See table 74 and figure XII.)

Total gross consumption of energy per unit of gross product in 1955 continued to follow the slight upward

Figure XII
LATIN AMERICA: EVOLUTION OF GROSS
ENERGY CONSUMPTION AND OF
ELECTRICITY PRODUCTION

(1950 = 100)
Semi-logarithmic scale

trend apparent since the mid-forties. The rate of growth was 1.2 per cent in 1955, slightly above the cumulative annual rate of 1.1 per cent registered for 1946-55.

For total and *per capita* electricity production a similar situation was apparent: the 1954 rate of growth—slightly above the historic rate over the period 1937-55—was maintained in 1955, thus offsetting the 1953 decline. Electricity output per unit of product grew in 1955 a little more rapidly than in previous years.

Hence it is clear that 1955 witnessed at least a slight improvement in Latin America's supply of electricity. However, deficits were still high in many urban centres (300,000 kW in Greater Buenos Aires, and nearly 500,000 in São Paulo), and relatively large in other places (Quito and some Colombian towns). These deficits stand in the way of economic development and compel industry to install its own equipment, which is an uneconomic solution, except in cases where the location, the type of process or the nature of the activity concerned necessitates its adoption.

Consequently, the production of electricity must in future maintain a high rate of growth if these accumulated deficits are gradually to be met and supply is to keep ahead of demand.

The higher ratio between aggregate electricity produced and total gross energy consumed indicates the greater electrification which has been steadily taking place, but which was more pronounced in 1954 and 1955. In this latter year the index rose to 115 (1950 = 100), corresponding to 459 kWh per kilogramme of petroleum.

It should be recalled, however, that average variations in the coefficients of unit consumption of energy for a region such as Latin America, which includes countries with different economic structures and with very uneven

rates of growth, conceal differing and even opposing patterns for each individual country. For instance, in economies based on mining and at an intermediate stage of development, like that of Chile, energy consumption per unit of product gradually decreased until 1954, because of the relative decline in mining, an activity in which energy consumption is intensive. In 1955, owing to the sharp upswing in mining, the coefficient also rose. The case of Argentina is diametrically opposed to that of Chile. Since economic growth there was based on agriculture, a sector where energy consumption is low, industrialization has resulted in a higher total consumption per unit of product. Nevertheless, the predominance of light industry—where energy consumption is not very high—combined with the relative mechanization of agriculture and a comparatively advanced level of technology, implying greater utilization of energy, has meant that the value of unit consumption has remained fairly constant, with only minor fluctuations.

In those agricultural countries entering upon a stage of incipient industrialization the coefficient under analysis increased rapidly, and continued to do so in 1955, as may be observed, for instance, in Central America. (See table 75 and figure XIII).

Greater energy consumption was recorded particularly in industry and mining, which offset the lower relative consumption in the other sectors.

Parallel to the 6 per cent increase in Latin America's energy consumption between 1954 and 1955, the gross product rose by approximately 5 per cent, although its growth rate was 6 per cent for manufacturing industries and 15 per cent for mining. The importance of these two sectors is patent, since their expansion in 1955 accounted for about 50 per cent of the total increase in energy consumption, even though their share in gross production does not exceed 25 per cent of the Latin American total.¹

¹ The increase in average energy consumption depends to a very large extent on activity in those sectors with the greatest specific consumption. Thus, the region's 1955 output in mining, non-ferrous metals, metallurgy, steel making and semi-finishing of steel, cement, pulp and paper, sugar extraction and petroleum output and refining showed an average increase of 10 per cent—35 per cent in iron ore mining and 50 per cent in the copper industry—and accounted for approximately 15 per cent of total energy consumption.

The country-by-country analysis will make this dependence even clearer.

In Brazil, the gross product of industry and mining rose by 5 per cent and that of agriculture by only 1

per cent, while energy consumption increased by 6 per cent. In Venezuela the 14 per cent and 11 per cent increments in the gross product of mining and industry respectively, were accompanied by a 20 per cent expansion in energy consumption. The disproportionately high figure for energy was due to the greater volume of domestic petroleum refining. Something similar happened in Colombia; although the product of mining and industry remained practically constant, the 8 per cent increase in energy consumption arose from additional petroleum refining and the establishment of the steel industry. In Chile, energy consumption rose by 6 per cent, largely through the substantial increment of 20 per cent in the product of mining, which offset the 7 per cent decline in that of industry. In Argentina, the growth of energy consumption was far less than that of the product (7 per cent in the case of agriculture and 11 per cent for mining and industry); this may have been because the increase in the product was mainly recorded in light industry and was partly brought about through a better use of equipment and improved productivity, which had no effect on energy consumption.

Information available for Argentina and Brazil concerning the distribution of energy consumption by sectors also confirms these observations. (See tables 76 and 77.) In 1955 (the difference in relation to 1954 is very slight), the industrial sector absorbed 33 per cent of all energy in Argentina and 34 per cent in Brazil.² In Argentina—where figures for earlier years are available—it may be seen that in 1948-55 the share of industrial consumption of energy in the total fell by 3 per cent,

² As regards Brazil, electricity shows the higher proportions and the more rapid increase. Thus, in 1955, industries in São Paulo consumed 14 per cent more electric energy than in the previous year, as against an over-all increase of 10 per cent.

although there was a 15 per cent expansion in the volume consumed.

The composition of aggregate energy consumption was much the same as in 1954. There was still a slight trend towards increased electrification and a greater dependence on petroleum, whether in the form of heavy derivatives or of those used for road transport, although the latter's rate of growth declined in some cases and in others barely remained constant. This higher consumption of heavy petroleum derivatives follows the trend recorded for some years; apart from tending to absorb almost all new demand—which can be met only to a very small extent by hydro-electric resources—they are also displacing other fuels, particularly coal and vegetable fuels. The trend in question has been sharpened by the favourable exchange and price policies usually adopted for these fuels, although in some cases the situation altered in 1955 or the early months of 1956.

Petroleum derivatives, after rapid expansion, levelled off at 75 per cent of the total for commercial energy;³ the slight upward trend observed in recent years slackened in 1955.

In some countries the rate slowed down a little for various reasons, a major role having perhaps been played by the shortage of foreign exchange to cover petroleum

³ Almost everywhere in the world petroleum consumption grew more rapidly than that of other products (and of total energy). Over the last five years consumption of petroleum in Western Europe and Asia increased three times more than that of total energy. The increments were much smaller in those countries where petroleum already represented a considerable share of aggregate consumption, the growth being slightly below that of total energy. For the whole world, the share of petroleum and natural gas in commercial energy consumption stands at 39 per cent (76 per cent in Latin America, 63 per cent in the United States and 17 per cent in Europe).

A yield of 4,500 Cal/kWh was adopted.^b Includes charcoal.^c Partial percentages have been omitted.^d Fuels for generating thermic electricity have been excluded to avoid duplication since the electricity produced has already been considered. In 1955, they were: petroleum derivatives, 770; mineral coal, 130; wood, 80 (all in thousands of tons of petroleum equivalent).

imports. Petroleum occupies a different place within aggregate consumption from one country to another. With the inclusion of vegetable fuels it represents about a third of the total, but, if they were excluded, the corresponding proportion would be as high as 80-90 per cent in many countries, and would, as a rule, exceed 50 per cent. (See again table 75.)

3. PRODUCTION AND CONSUMPTION OF PETROLEUM AND ITS DERIVATIVES

The increase in the output of crude petroleum has been less than the growth in the consumption of its derivatives; this is true of all the Latin American countries, except Bolivia and Venezuela. Consequently, in 1955 they were obliged to raise their imports of hydrocarbons above the level of the previous year. But the pattern of these imports changed, because increased refining capacity led to a reduction in the purchase of derivatives, and, on the other hand, to heavier purchases of crude oil.

In the course of 1955, transport deficiencies caused serious difficulties. The higher freight rates had direct repercussions on the cost of imported products, since national tanker fleets were small. Moreover, a lack of pipelines limited and even prevented the exploitation of some oilfields.

Crude oil production in the whole of Latin America, except Venezuela, increased by 6 cent in 1955. In Venezuela, where output represented 15 per cent of the world total, the expansion amounted to almost 14 per cent. Thanks to Venezuela's contribution, Latin America maintains its world position as a producer, but, excluding that country, its share in 1955 would have fallen by 10 per cent.

Extraction remained practically stationary in Colombia and Peru, but showed a very slight rise in Argentina

and an increase of 7 per cent in Mexico. Ecuador, after many years of slow growth, achieved a substantial increase in production (12 per cent). Increments in Bolivia, Brazil, Chile and Cuba—although small in absolute terms—represented very high percentage rates of growth. (See table 78.)

In 1955, except in Bolivia and Venezuela, the growth in domestic production of crude oil did not suffice to meet that year's higher requirements. All the region's producers, excluding Venezuela, witnessed increments in consumption which exceeded those in production by more than a million tons, a volume equivalent to about 40 per cent of the total increase in consumption. As a result, it was necessary in some cases to reduce the net exportable surplus and in others to resort to larger imports. (See table 79.) Thus, while production rose by about 1,540,000 tons for the whole of Latin America, excluding Venezuela, aggregate consumption increased by 3,060,000 tons of petroleum equivalent.

In order to meet the growing pressure of demand for petroleum derivatives, many countries have attempted to ensure that future expansions of the production of crude shall be at least approximately equal to the increase in demand. Given the ever-growing gap between demand and output, these efforts, although intensive, have been insufficient. Despite continued geophysical and geological prospecting, as well as additional drilling of wells, both for exploration and production purposes, and although many countries have reorganized their system of concessions on a more liberal basis, there has been no satisfactory increment in output. The rate of growth for drilling has been fairly high (10 per cent annually since the end of the Second World War, which is close to that of the United States) and by the end of 1955 there were nearly 13,000 wells in production, always excluding Venezuela. The failure to achieve any proportional increase in extraction may be due to the variety of systems employed, to the relatively low yield of the wells and to

^b Including crude oil corresponding to derivatives exported.

^c Excluding Cuba.

the fact that in absolute terms their number is too small to permit of it.

In 1955, some importers of fuels laid the foundations for an improvement in their future production prospects. Of particular importance in this connexion is Argentina's statement that it is hoped to produce 3 million more cubic metres of petroleum and natural gas by 1958-59. Chile in its turn considers that by 1958 most of its consumption requirements can be covered by domestic output, excluding the demand of the large mining companies.

The greatest progress in 1955 was achieved in the refining of national crude resources. Indeed, the increases of 23 per cent (including Venezuela) and 24 per cent (excluding Venezuela) recorded here are far higher than the rates of growth attained by extraction and consumption. The increments were extremely large in Brazil and Chile and were substantial in Bolivia, Colombia and Venezuela. They confirm the world trend towards more refining of crude oil in the countries where the products will be consumed.

By 1955, countries such as Argentina and Uruguay were already refining sufficient supplies to meet almost all their needs, while domestic refineries satisfied 40 per cent of all consumption in Brazil and 35 per cent in Chile.

Moreover, installed refining capacity was used to greater advantage in nearly all the countries. The degree of utilization in Brazil and Chile rose from about 10 to 65 per cent. (See again table 78.) In Bolivia and Colombia there were sizeable increases. But these improvements in utilization may give a false impression because they were achieved in plants which were completed in 1954 and did not operate at full capacity until the early months of 1955, or even later. Much the same was true of Argentina and Mexico in 1955. In Ecuador, Uruguay and Venezuela, the volume of refining exceeded the installed capacity, which clearly indicates the pressure exerted on existing installations and the need to

expand them. Towards the close of the year, Latin America was installing new capacity equivalent to 23 per cent of that in operation to date; if Venezuela is excluded, this proportion falls to 18 per cent. The plants under construction and existing projects mean that a considerably increased rate of refining may be expected during the next few years.

Because of the additional domestic refining of crude oil from both national and foreign sources, some imports of derivatives were replaced by crude oil, which was cheaper. Thus in 1955 crude oil represented 38 per cent of the total volume of imports of hydro-carbons, as compared with 25 per cent in 1954. (See again table 79.)

The installation or expansion of petroleum cracking plants permitted imports of petrol and other light products to be reduced. This was the case in Colombia, where petrol imports declined by 34 per cent, despite higher consumption. In Argentina, however, imports of derivatives rose more than those of crude oil (through insufficient domestic production of heavy and medium derivatives); in Peru imports of fuel oil trebled, while exports of gas and diesel oil more than doubled, a situation which had obvious economic benefits.

The relationship between the consumption of fuel oil and petrol altered a great deal in favour of the former, thus confirming the growing importance of energy replacement. (See tables 80 and 81.) Consumption for motor vehicles rose less (except in Colombia, Ecuador and Venezuela), although at the same time an increase in the consumption of diesel and gas oil for such vehicles took place.

It is interesting to note that, following the United States pattern, consumption of light derivatives (diesel and gas oil) has for more than twenty years been outstripping that of the heavier product (fuel oil). This is probably a consequence of the trend towards a greater use of diesel locomotives for railway transport and of the larger number of vehicles using gas oil instead of motor spirit.

Source: Official data.

Transport of crude oil, derivatives and natural gas continued to be a critical problem for some countries. The severe winter of 1955-56 in Europe led to shipping transport shortages for the Latin American countries and this resulted in higher freight rates. Since most of Latin America's imports of crude are carried by sea and are exported by the major producers of the region⁴—mainly Colombia and Venezuela—it is clear that inter-Latin-American transport should be rendered more independent through the provision of larger tanker fleets.

In addition, existing difficulties in the land transport of petroleum have greatly hampered the production possibilities of some countries, apart from hindering the normal supply of fuels for domestic consumption. Bolivia is geographically well situated for meeting some of the petroleum needs of its importing neighbours, but in addition to larger output, a system of pipelines, the cheapest and safest means of transporting liquid fuels, is required. The Mendoza oilfields, in Argentina, were obliged to limit their output to half a million cubic metres and the Campo Durán fields have not yet entered production for lack of transport. At the Bahia reserves in Brazil, only one-third of the potential productive capacity, or 2,500 cubic metres daily in 1955, could be utilized, and a peak cannot be reached until the 50-kilometre pipeline to the port of Madre de Dios is completed; this pipeline will allow crude oil to be transported to the southern refineries of Brazil.

The additions to Latin America's pipeline network made in 1955—or the continuation of work under construction—represented a substantial contribution to the region's petroleum system in real though not in percentage terms.

In Bolivia, most of the year's investment in the petroleum sector was for pipelines. The largest, which runs from Cochabamba to La Paz (6 inches and 370 kilometres) was begun and completed during 1955, and replaced expensive rail transport. The town of Cochabamba, where the pipeline begins and which has a refinery, is linked with the Camiri field, so that petroleum can reach the Altiplano area. Thence it will be exported to the Pacific through a new pipeline—the building of which has already been agreed upon—to the Chilean port of Arica. At a later stage, the producing fields are to be linked directly with the city of Sicasica (on the Altiplano) by means of a pipeline with a daily capacity of 8,000 cubic metres. To facilitate sales to Argentina, another pipeline (6 inches and 254 kilometres) was begun in 1955, which will link the Camiri fields with the frontier centre of Yacuiba and will be prolonged another 27 kilometres to Aguarray (Salta). The results cannot be very effective yet because it is difficult to ensure transport to the main consuming centres in Argentina.

Colombia—where, as in Bolivia, the topography causes serious transport difficulties—has solved the export problem by means of a trunk pipeline, 538 kilometres long, from the two largest producing centres to Puerto Mamonal (Cartagena) on the Caribbean and by the completion of the Galán-Velázquez line (12 inches and 180 kilometres), which will enable the output of this latter

⁴ Of Latin America's imports in 1955, half the crude and 85 per cent of the derivatives came from Latin American countries. The remainder of the derivatives and 15 per cent of the crude were imported from the United States.

field to be increased. Obstacles to domestic supply have been partly overcome by the opening of the pipeline from Puerto Berrio to Medellín (6 inches and 180 kilometres). Moreover, there are plans to link Buenaventura with Cali by a pipeline (6 inches and 100 kilometres).

The two pipelines built in Ecuador and Peru, both of some 75 kilometres in length, were less important than those in Bolivia and Colombia.

Except in Mexico, there were scarcely any additions to the existing network of natural gas pipelines in 1955. The shortage of tubing for pipelines—which it is hoped to overcome in the near future⁵—has helped to aggravate the deficit in the local supply of hydro-carbons in some countries.

In Mexico, the industry has been obliged to increase overland transport for petroleum products because of the steady expansion of the domestic market. As a result, 1955 witnessed the completion of the pipeline from Poza Rica to Atzacapotzalco (16 inches and 236 kilometres), which raised the pumping capacity from this field to the capital to 24,000 cubic metres daily. Combined with this pipeline is a propane pipeline with a daily capacity of 480 cubic metres. During the year the daily capacity of the Minatitlán-Salina Cruz pipeline was doubled and now stands at 5,000 cubic metres. The policy in Mexico is to expand the pipeline network and, in addition to the construction of new pipelines, it is planned to build new connecting links. Among these is the Tampico-Monterrey line (12 inches and 490 kilometres), which will be used for transporting refined products, and that from Angostura to Veracruz (20 inches and 80 kilometres) to carry crude oil. Both pipelines are designed to transport 4,000 cubic metres daily, but the former can be enlarged to double its capacity. Pipelines to connect Salamanca-Aguascalientes-Zacatecas and Monterrey-Torreón are under construction, while plans include a branch from Rei-

nosa to Monterrey and the extension to Chihuahua of the Monterrey-Torreón pipeline.

4. PRODUCTION AND CONSUMPTION OF ELECTRIC ENERGY

Increases in electric generating capacity—which were slightly greater for hydro-electric than for thermic plants (see tables 82 and 83)—and the improvements in the linking up of some zones, led in 1955 to considerably increased production of this type of energy in Latin America; but even so, all the regional deficits which existed in 1954 have not yet been eliminated.

Although electric energy production was raised by means of increases in the generating capacity, it did not suffice to meet demand and, apart from a few exceptional cases, could not cover accumulated deficits. The shortages were particularly acute in some of the larger urban centres, while supplies in many rural zones showed considerable improvement. It seems probable that, had an ample supply of electric energy been available, industrial output would have grown far beyond the 1955 level and substantial economies in fuel or energy could have been achieved through electrification of overloaded sections on some railways. In Mexico, out-of-date and highly uneconomic units for thermal electricity were taken out of operation (to total of 56,000 kW); their consumption per kWh was double or even three times that of more modern units. The fact that this could not be done in other countries has meant the retention of one more cause of poor utilization of energy and low efficiency.

Although official attention is increasingly focussed on the utilization of the sources of hydro-electric energy, these increased to a very small extent in proportion to the total, partly because hydro-electric undertakings were not completed or there were as yet no transmission lines, as for instance at Nihuil (Argentina).⁶ The situation by

⁵ In Argentina, for instance, it is expected to finish what little work is still pending on the gas line from the south to Buenos Aires and the building of another pipeline from the north.

⁶ The thermic plant at San Nicolás presents a similar case, because, for lack of transmission lines, it must remain idle for most of the time.

^c It is estimated that private power plants under construction reached a total of approximately 150 thousand kW at the end of 1955.

countries has not changed, so that thermic energy continued to predominate over hydro-electricity in Argentina, Mexico and Venezuela, but not in Brazil, Chile, Peru, etc.

But there are some countries where sources of hydro-electric energy near densely-populated centres are becoming exhausted and others where a large economic potential exists and in several cases, interconnexion has overcome difficulties arising through water shortages or increased consumption (Rio de Janeiro-São Paulo area; central zone of Chile).

Inadequate rainfall in some areas of Latin America—for instance, in several Mexican states and parts of São Paulo State in Brazil—affected energy supplies by reducing the level of water in hydro-electric reservoirs. This factor once again emphasizes the desirability of improving and stabilizing effective hydro-electric potential by regulating water courses, building compensatory reservoirs and interconnecting, as far as possible, zones with differing rainy or thawing seasons. Little progress was made in this field during 1955, although plans are being made to remedy the situation. Exceptions are the interconnexion of plants in the central zone of Chile, the reinforcement of the links between São Paulo and Rio de Janeiro in Brazil and the interconnexion of the central system in Mexico.

As regards the use of hydro-electricity, in spite of increased production and consumption in absolute terms, its percentage share within the total consumption of

commercial energy has remained practically unchanged over the last five years. (See again tables 74 and 75.) Prospects are improving, owing to the work under construction, to greater activity in prospecting for hydraulic resources and to the selection of better sites for immediate utilization, although not many complete draft projects exist. Governments are also concentrating more attention on works aimed at the multiple utilization of hydraulic resources. The major event of the year in this sphere took place in Colombia, where the recently-created Comisión Autónoma del Valle del Cauca has just completed the first stage of its programme for the development of the river basin, involving 220,000 kW of energy by 1962 and 290,000 hectares under irrigation. At the same time, work continued in Mexico in the valleys of Papaloapán and Tepalcatepec. In Peru, renewal of work in the Río Santa revives the possibility of this region's integral development in the near future.

Apart from the common difficulties described, each country has its own peculiar electricity problems. In Argentina, for example, the pronounced shortage which had been apparent for some years continued in 1955. Unsatisfied demand is particularly acute in Greater Buenos Aires, where consumption represents 70 per cent of the national total. The deficit in this zone, estimated at 300,000 kW, over and above the existing 840,000 kW, has led to the introduction of severe restrictions and no new connexions are authorized.

The supply of electric energy in Bolivia improved in the capital, where the company holding the concession

brought into operation units for slightly over 8,000 kW to supplement existing hydro-electric sources. Additions elsewhere in the country were of very little significance.

The serious problem of the lack of electricity in Brazil during 1954 was partly solved in 1955; rationing was temporarily lifted in Rio de Janeiro and to a lesser degree and more irregularly in São Paulo, despite increased consumption.⁷

Chile's electricity supplies improved in 1955 with the inauguration of the interconnexion system in the central zone and the entry into operation of the new hydro-electric power plant at "Los Cipreses", which has a capacity to 104,000 kW.⁸ The Government of Chile, because of delays in the programme for expanding installed capacity, decided to continue the rationing of electricity consumption in the central provinces during the winter of 1956 along lines similar to those followed since 1953, with a view to controlling the growth of demand until such time as it can be fully covered.

Colombia made some progress in reducing the acute shortages of electric energy in industrial zones and in extending the supply to new areas and municipalities. However, some of the large towns (Bogotá, Cali, Medellín), were still in a difficult position.

In Mexico, the aggregate electricity supply in 1955 exceeded the high rates of growth of previous years. Even so, owing to a fall in the water level of the hydro-electric reservoirs, serious problems arose in connexion with the supply of electricity to the States of Jalisco, Michoacán, Guanajuato, Querétaro and San Luis Potosí. The rate of increase in installed capacity (7.3 per cent

if equipment withdrawn from service is included) was lower than during the previous five-year period (9.2 per cent annually), because certain large projects were completed in 1950-52.

Whereas energy shortages persisted in Ecuador, Guatemala and Honduras during 1955, electricity production in Uruguay and Venezuela kept pace with demand.

5. THE SUBSTITUTION PROCESS WITHIN THE ENERGY SECTOR

Stationary coal consumption and a slight decline in the demand for vegetable fuels are indications that these forms of energy are being displaced, particularly by fuel oil and natural gas. This substitution is caused not only by technical advantages—which are particularly obvious for railways and in the thermic generation of electricity—but also by the fact that price policies usually favour hydro-carbons.

The replacement of coal in certain activities by natural gas or fuel oil is evidenced in that its use in Latin America has declined in percentage and, at times, in absolute terms. Aggregate consumption rose by only 25 per cent from 1954 to 1955. (See table 84.) With the exception of Colombia, where the production level rose by 20 per cent over 1954, the situation in all the other countries remained practically unchanged; the increase amounted only to 2.5 per cent, which reveals a general stagnation. Imports as a rule declined, and in some cases sharply, as in Argentina. One of the few exceptions was Brazil, where imports rose by nearly 25 per cent, largely because of the expansion of steel making.

Table 84. Latin America: Coal situation^a

Source: National statistics.

^a Coke is included in imports.

^b Imports of other countries not specifically listed are included.

Production in several countries remained stationary, reflecting the serious setbacks encountered by the coal industry. Among the obstacles common to many countries were the absence of mechanization, transport and washing plants, while difficult conditions at the mine faces and the dispersal of operations over a large number of small workings also hindered output. To

overcome the problems, substantial investments in the different items would have been necessary and, if they had been made, would have helped to reduce the high market price of coal.

The development of Latin America's heavy industry is becoming a focal point for coal mining. Almost 10 million tons of coal were consumed in 1955, of which no less than 1.5 million tons (or over 15 per cent of the consumption during that year) were used for metallurgical coke, mainly for the steel and rolling mills. In Brazil, for instance, coal consumption for metallurgical

⁷ Notwithstanding the considerable increase in capacity achieved, it is estimated that early in 1956 there was still a large deficit which will be partly covered by the plants currently being constructed.

⁸ For details of this plant, see p. 93.

purposes represents nearly 20 per cent of all coal consumption; in Chile, 16 per cent; and in Mexico, 35 per cent. In addition, over half a million tons of charcoal were also used for steel making, mainly in Argentina and Brazil, and this figure is rising.

The downward trend in vegetable fuel consumption, particularly since the war, has already been mentioned. No quantitative assessment can be given for most of the Latin American countries because statistics are not available; but in both Argentina and Brazil the decrease amounted to 2 per cent during the period 1954-55, and reflected the natural trend towards modernizing fuel-burning equipment. Nevertheless, the remoteness of the sources of supply, together with transport difficulties, which result in relatively higher prices for vegetable fuels in centres far from the source, has meant that their use often declines with greater rapidity than would have been desirable from the economic standpoint. In fact, this decrease has had to be compensated with petroleum derivatives which are frequently imported, thus causing serious balance-of-payments difficulties in some countries.

It is interesting to note the higher consumption of natural gas, particularly in Argentina, Mexico and Venezuela, not only at the oilfields and the refineries in their vicinity, but also in industrial and urban centres. In 1955, the residential use of natural gas rose by 3 per cent in Argentina and 7 per cent in Venezuela. Moreover, there is a growing rapid increase in the use of liquid gases derived from petroleum, which are more easily transported in containers in many towns which previously lacked such facilities.

Residential consumption of refinery gas—either liquid, for mixing with coal gas, or the original gas—increased during 1955 in proportions of 62 per cent in Brazil, 43 per cent in Colombia and 12 per cent in Peru. Particularly noteworthy was the strong impetus given to such consumption in Argentina, Brazil and Colombia. Similarly, in Chile there are plans to construct a pipeline from the Concón refinery to Valparaíso and Santiago to supplement the supplies from existing sources; some of the gas will be sold in containers. In Argentina and Uruguay all refinery surpluses are at present employed and the utilization of gas transported in containers is widespread.

Some consideration may be given to the reasons why petroleum derivatives are so rapidly replacing coal and vegetable fuels. The technical superiority of hydrocarbons over solid fuels is well known; they are easier to supply and handle as well as more efficient and economical in use. There are also specific technological advantages of a different kind, which only become evident through the use of hydrocarbons, as in the case of Diesel locomotives, whose suitability for haulage purposes contributes greatly to fuel economies. Price relations between the different fuels, which usually favour petroleum derivatives, emphasized the trend; so did the more reliable guarantees of a regular supply to the consumer.

The rapidly increasing substitution of Diesel units for steam engines, together with the more intensive utilization of the former and the partial transformation of coal or wood furnaces to fuel oil burners, is contributing more and more to the predominance of petroleum consumption. Data available for several countries show that

coal and wood consumption in 1955 declined or remained stationary on the railways. On the other hand, the increase in thermic generation of electricity—which may perhaps have been effected almost entirely through the greater use of fuel, Diesel oil and, at times, natural gas—helped to raise the level of demand for these petroleum derivatives. Moreover, the growing consumption of natural or liquid gas from refineries limits the use of coal for producing gas and even threatens to eliminate it.

Price policy is a weighty factor in the above examples of transport and electricity production, but it is not decisive for industry in general because of the relatively small incidence of the price of energy upon the cost of the product.

There is no constant ratio in Latin America between coal and fuel-oil prices, when both are expressed as equivalents of potential energy; generally speaking, however, the latter is much cheaper than coal, just as it is in the United States.

In addition, there were very unequal variations in the prices of the various forms of energy during 1955. The changes were not even uniform within any one given country and were rarely adjusted to variations in the cost-of-living index. Although, broadly speaking, increases in fuel-oil prices were slight, this was not the case with medium derivatives (Diesel and gas oil) where very high percentage rates were attained. The abnormal price ratios which had existed between these fuels and had led to an undesirable trend in consumption, were corrected by these adjustments.⁹

The disparity in relative prices was on occasions due to a policy of indirect government subsidies or bonuses to petroleum producers or consumers, granted through preferential exchange rates for imports of crude oil and petroleum derivatives. The rates so fixed are usually lower than the average rate applied to imports. Hence these fuels in fact receive a subsidy and their consumption is encouraged, so that in some cases they are in an advantageous position in relation to domestic fuels, particularly coal. Had this preferential rate not been applied, fuel prices would have been considerably higher. Argentina, where the exchange rate which had governed imported fuels was eliminated and the uniform official rate was applied to them, provides evidence of this fact.

6. PETROLEUM AND THE EXCHANGE BUDGET

The growing increase in petroleum consumption has led to difficulties in those countries where it has been unaccompanied by a corresponding rise in domestic production. As a rule, supply has kept pace with demand, but not without some sacrifices in countries such as Argentina, Brazil and Chile. Fuel imports in these three countries have expanded much faster than the capacity to import, thus exerting considerable pressure on the balance of payments. Moreover, fuel purchases have been made at the expense of capital goods imports essential for accelerating economic development. During 1955, Latin America's fuel imports (736 million dollars) amounted to 10.2 per cent of all purchases abroad, whereas the corresponding proportion was 9.2 per cent in 1951-54. (See table 85.)

⁹ In the early months of 1956, adjustments of this type took place in Argentina, Brazil, Chile and Ecuador.

Table 85. Latin America: Incidence of fuels on the value of all imports in selected countries

(Percentages)

Years	Argentina	Brazil	Chile	Cuba	Uruguay	Total Latin America
1934-38	8.3	12.4	7.9	5.9	4.8	—
1946-50	11.6	10.5	10.1	5.0	7.3	—
1951-53	19.6	12.8	11.2	7.3	10.4	9.2
1954	18	18.7	15.5	10.8	13.0	9.3
1955	13.4 ^a	21.7	15.4	12.9	13.0 ^b	10.2

Source: National statistics.

^a The decline was due to the substantial increase in all Argentine imports, since the value of fuel imports remained constant.^b Estimated.

Although these aggregate figures provide some general idea of the magnitude of the problem, they are insufficient to show what effect the measures adopted to solve it will have. For this purpose some individual cases should be studied in more detail. The considerable increase in refining capacity achieved in Latin America has favourably influenced exchange savings. Even though the refineries have to use imported crude oil, their operation saves any given country a considerable sum of foreign exchange; this saving is naturally greater when the complete cycle—from the extraction of crude oil to the production of derivatives—takes place within the national territory.

Brazil and Chile provide good illustrations of the effects of domestic refining and production of petroleum. In Brazil, the three plants which were in operation in 1955—Presidente Bernardes, Capuava and Marguinhos—refined 3.5 million cubic metres of crude oil in the year, with a value of 70.5 million dollars. It would have cost 87.2 million dollars to import the derivatives made from this crude oil. Gross savings in exchange were thus 16.7 million dollars. Since the external commitments involved in the building of these refineries amounted to 60 million dollars—that is, two-thirds of the total investment—they can be amortized in three or four years simply through the foreign exchange saved.

A further case in point is that of Chile. Production at the Concón refinery required the investment of 10.5 million dollars and led, in 1955, to exchange savings of approximately 3 million dollars.

Domestic production of crude petroleum naturally increases the economy in foreign exchange. In 1955, the extraction of 321,000 cubic metres in Brazil and 410,000 cubic metres in Chile represented decreases in foreign currency expenditure of 6 and 8 million dollars, respectively. When these figures are compared with the exchange saving effected through refining, it may be seen that crude production has led to an economy almost four times greater than that obtained by refining the same volume of imported petroleum.

7. THE EVOLUTION AND FINANCING OF ENERGY INVESTMENT

The capital invested in Latin America during 1955 to raise energy production constituted a large share of total investment in the region; it was also comparable to such

investment during the immediately preceding years. If all activities related to electricity and fuels are taken into account, even those which only represent exports, as in the case of most of Venezuela's petroleum, a figure of approximately 1.2 billion dollars for gross investment in 1955 is reached. This is nearly 14 per cent of the estimated 8.7 billion dollars invested in Latin America's economy during the same year. Of the investment in energy, approximately half corresponded to public resources and the other half to private capital, mostly of foreign origin. Their relative shares varied according to the branch concerned; for instance, official public enterprise represented 75 per cent in electricity and 29 per cent in petroleum. By subtracting from total petroleum investment the amount required to produce petroleum exports—which corresponds mainly to Venezuela—the investments that were needed to ensure supplies for the region can be established. (See table 86.) The result is 875 million dollars, or 10 per cent of total gross investment. This representative percentage should be regarded as approaching that required to maintain the rate of energy supply in Latin America. In point of fact, countries such as Chile and Mexico, with active national electrification programmes and development projects for their fuel reserves, have in recent years devoted 10 to 12 per cent of their domestic capital formation to energy purposes.

Table 86. Latin America: Total investment in energy for domestic supply, 1955^a

(Millions of dollars)

	Public	Foreign private	Others ^b	Total	Percentages
Electricity:					
Public service..	365	100	20	485	56
Private facilities	—	20	10	30	3
Petroleum	200	145	5	350	40
Coal	5	—	5	10	1
TOTALS	570	265	40	875	
Percentages	65	30	5	—	100

Source: National data.

^a If that share of investment in petroleum which was used for exports outside Latin America is included, the amount corresponding to foreign private enterprise in petroleum rises from 145 to 485 million dollars. The total for petroleum would thus increase from 350 to 690 millions and the grand total of 875 million would rise to 1,215 million dollars.

^b Represents local private capital and small municipalities.

Needless to say, investments in the larger countries considerably influence the regional total. Since investment was relatively low in Argentina during 1955 and also fell off somewhat in Brazil because large electrical projects had been completed, the percentage for the rest of Latin America may perhaps be a little higher. On the basis of these approximate global figures, it seems clear that the regional effort in the field of energy is proportionate to the available means. But this does not necessarily mean that all problems have been solved, particularly in the large urban areas where great pressure was still exerted by demand.

The composition of gross annual investment in energy for domestic consumption reveals that nearly two-thirds—570 million dollars—represents the operations of large bodies established in several countries to organize the systematic development of national energy supplies, and financed by public funds. The electricity sector, because its tariffs do not follow the rise in the cost of living, has usually been the least attractive to private capital; as a result it has been the primary object of official efforts, and received 64 per cent of total public investment in energy in 1955. The 570 million dollars involved constituted 22 per cent of gross annual public investment in the economy of the region as a whole, which was estimated at 2.5 billion dollars. This reflects the greater relative importance attached to energy by the public sector, since, as indicated above, the private capital thus invested absorbed only 10 per cent of aggregate national investment.

Almost half the capital formation by foreign private investors corresponds to United States and Canadian companies which hold concessions for the electricity supply in many capitals and large towns; the remainder is accounted for by foreign corporations which serve local markets with domestically produced or imported petroleum.

Electricity companies obtained more credit for their development than during 1954, in both foreign and local currencies.

International official loans granted for energy in Latin America during 1955 amounted to 17.5 million dollars from the International Bank for Reconstruction and Development and 26.6 millions from the Export-Import Bank. The combined credit exceeded by 16 per cent that granted by these institutions in 1954, but there was some variation in their respective contributions: in 1955 the International Bank provided only half as much capital as in the previous year; conversely, the Export-Import Bank had loaned only 750,000 dollars in 1954.

The International Bank conceded a loan of 4.5 million dollars to the autonomous enterprise which was established with public funds to supply electricity to Cali (Colombia). This sum is to be devoted to expanding by 20,000 kW the Achicayá plant—for whose first 24,000 kW, recently inaugurated, the same Bank provided credit—and to the installation of a 12,500-kW thermal plant at Yumbo, which will operate with domestic coal. A further 5.5 millions were granted to Usinas y Teléfonos del Estado, in Uruguay, for a third 50,000-kW unit in the thermo-electric plant at Montevideo, the second unit of which had also been installed with the aid of the bank. Finally, 7.5 million dollars were loaned to Nicaragua

for a new 30,000-kW power station and its distribution network in the Managua zone. These loans brought the total authorized by the International Bank for Reconstruction and Development for the expansion of Latin America's electric energy to 307 million dollars, or approximately 46 per cent of the total granted throughout the world for electricity, and 49 per cent of the aggregate loans assigned to Latin America.

Export-Import Bank credits for energy included 2.5 million dollars for the power station in Nicaragua mentioned above, and 1 million to the Instituto Costarricense de Electricidad for the purchase of generating equipment based on Diesel engines. The remaining 23 millions were used for the expansion programmes of Mexican power companies financed by foreign funds. This Bank's total outstanding loans to Latin America for electricity supplies amounted at the beginning of 1956 to 160 million dollars, or 10 per cent of all its loans to the region.

Among the operations of those national institutions which grant credit from public funds for the development of electricity supplies, the work of the Banco do Desenvolvimento Economico of Brazil was important. Although the aggregate credit granted by this bank fell considerably in 1954-55, loans for electric energy rose by 44 per cent and amounted to 1.57 billion cruzeiros (approximately 34 million dollars),¹⁰ which absorbed 46 per cent of the bank's loan capital. This financing has benefited private enterprise, both national and foreign, as well as para-Statal organizations.

The Nacional Financiera in Mexico also finances light and power companies formed with official and private capital and almost 16 per cent of its loans and investment was used for this purpose.

In Chile, the national electricity enterprise has been financed through the Corporación de Fomento, which has channelled all its financial aid to the sector in question through this body. Such contributions have recently been restricted through the shortage of official funds.

In Cuba, the Nacional Financiera has provided funds for energy development, among which is a long-term loan for 8 million dollars to the foreign concessionaire of the public service in Havana. Loans from the Banco Industrial in Argentina to a value of 350 million pesos were earmarked to help two power companies.

8. INVESTMENT IN ELECTRICITY AND PETROLEUM

It is interesting to evaluate relative contributions to the different undertakings in the sector of public electricity enterprises, where investment in 1955 was estimated at 470 million dollars. This sum corresponds to work which led to the installation during the year of a generating capacity of 690,000 kW and which, at the end of 1955, had 3.6 million kW in course of installation, for completion over the subsequent three or four years.

¹⁰ For the conversion of this sum, representing only local expenditure, a rate of exchange has been used which approximately represents the real par value of the foreign exchange. Other equivalents of investment will be found at a later stage, which include expenditure in foreign currencies that have usually been converted at the official rate.

The future programme, which represents the creation of almost 1 million additional kW annually, would increase the present capacity of 8.6 million kW at an annual rate exceeding 10 per cent. This is undoubtedly a good average for Latin America. If sustained for several years, it would raise the level of electricity consumption substantially, certainly above that observed during the period 1946-55, when the average rate of growth of electricity capacity for public use was 7 per cent annually.

From another angle, some 75 per cent of the total completed and under construction at the end of 1955 was the work of organizations financed with large public, state or municipal funds, which at present only account for 28 per cent (2.4 million kW) of the total installed to date. (See table 87.) These figures indicate the relatively rapid rate of development of such enterprises, which had only some 300,000 kW in operation in three countries (Chile, Mexico and Uruguay) ten years ago.

^a Including enterprises in which public funds have provided most of the capital either through autonomous agencies or national, provincial, state or municipal governments. Of the latter only those of some importance for the whole of the country are included, small municipal plants operated directly or through concessionaires in small communities not being taken into account.

^b Estimates.

^c Instituto Nacional de Aguas y Fomento Eléctrico and large municipal enterprises, such as those of Bogotá, Medellín, etc.

^d Includes the 5,000-kW project at Riobamba.

The investment placed by these organizations is directed mainly to the production of electricity, which is transferred in high-tension form to third parties who act as distributors. In this way it is hoped to establish a supply which will encourage the collaboration of private capital. This policy has yielded some results in Chile and Mexico. Nevertheless, it is sometimes becoming necessary—even in those countries—for official bodies to help to finance the distribution companies, or to take over the actual distribution activities to ensure that services will be available in new areas or that very large projects will receive adequate attention.

During 1955, the major responsibility for financing energy investment in Argentina was left to the State. In

consequence, the building of all new power plants is entrusted to Aguas y Energía Eléctrica, a national agency whose operations have not yet attained large proportions. In fact, during 1955 only a little over 50,000 kW entered operation, completing an installed capacity of 250,000 kW, or scarcely 12 per cent of the national total.¹¹

¹¹ In January 1956 some 600,000 kW were being installed. It is planned to invest the equivalent of some 63 million dollars in these plants, a figure similar to the 65 and 59 million dollars invested in 1954 and 1955, respectively. Apart from a large thermo-electric plant for the immediate relief of Greater Buenos Aires, Aguas y Energía Eléctrica is studying the development of major hydro-electric projects. Because hydro-electric energy sources are so far from the consuming centres, it can usually only be exploited in units large enough to ensure that it is economically worth while to install the necessary transmission lines.

Until the national agency provided for in the electrification plan is established in Brazil, autonomous regional bodies are responsible for any public investment in the sector. Some of these bodies exploit one specific resource, as in the case of the São Francisco river, where 60,000 kW were inaugurated in 1955, or of the Pardo river in São Paulo State, where the project concerned is under construction. Other new plants are State undertakings, like Minas Gerais, Rio Grande do Sul, Espiritu Santo, Bahia, etc., where a combined total of 420,000 kW was being installed at the end of the year.

During 1955, the Empresa Nacional de Electricidad in Chile put into operation a hydro-electric plant of 104,000 kW in the country's central zone, thus completing 310,000 kW (56 per cent of the total capacity for public service). The same company also inaugurated the large transmission system linking Santiago with a power plant located 533 kilometres to the south; this means that complementary water systems in the central and southern parts of the country can be combined and that the system's older plants can be repaired without interruption of the service.

During 1955, the Instituto de Aguas y Fomento Eléctrico in Colombia opened one of its first large projects. This was the initial stage of the Central Hidroeléctrica de Achicayá, of 24,000 kW, which will reduce the serious shortage in the city of Cali and has to date represented an investment approaching 18 million dollars.¹²

In Mexico, the Comisión Federal de Electricidad placed investments in 1955 representing the major share of a national total for energy of 599 million pesos (44.7 million dollars). This was 35 per cent more than peso investments in the previous year (in nominal terms), and helped the complete 135,000 kW during 1955, leaving another 550,000 kW under construction. The central grid was connected with the Bajío area and the new Michoacán plant was linked to Guanajuato and Chapala.

In Peru, the first stage in providing an output of 50,000 kW at the hydroelectric plant of Cañon del Pato is nearing completion. This plant is being constructed by the Corporación del Santa in the river valley of the same name. It will have a total capacity of 150,000 kW and is intended to encourage general economic development in the area. In particular it will supply the energy for the electric furnaces being installed locally. To complete the building of this power plant—which was interrupted after an avalanche had destroyed some of the installations—the Corporation has received a 15-million-dollar loan from a private European bank.

Usinas y Teléfonos del Estado, which is exclusively responsible for the electricity supply in Uruguay, did not inaugurate any new production facilities in 1955, but continued its over-all programme. This includes the immediate addition of 50,000 kW at the Montevideo thermic plant and the building of a second large hydro-electric plant on the Negro river.

The Corporación Venezolana de Fomento is also carrying out a national electrification programme, in which it invested some 4 million dollars during 1955. Only 4,800 kW were put into operation, but at the end of the year 95,000 kW were under construction and tenders for the installation of another 140,000 kW had been sent out. The first 100,000 kW of the hydro-electric plant on the Caroni river are also being established with public funds. This is the first large plant of its kind in the Corporation's programme, which, for obvious reasons, is fundamentally based on petroleum plants, and will serve to encourage industries, especially those manufacturing steel and chemicals.

Substantial public investment in electricity in Central America included that provided at the national level by the Instituto Costarricense de Electricidad, and capital which permitted the utilization of the River Lempa in El Salvador.

Plants financed by foreign capital constitute another important nucleus of light and power companies in Latin America. They combine to produce 4.6 million kW, that is, 53 per cent of the total for public use in the region, but in 1955 they contributed only 21 per cent of investment under this head. (See table 88.) Except in Argentina, these foreign companies have benefited from official policy and have announced development plans that will apparently be carried out within the near future.

The largest of these enterprises operates in the Rio de Janeiro-São Paulo area of Brazil, and is completing a large expansion programme to raise capacity by nearly 800,000 kW between 1953 and 1956. Next follows a United States company with plants in eleven Latin American countries; since 1945 it had invested over 380 million dollars in the installation of 475,000 kW, and it has now announced a 450-million-dollar programme for the production of an additional 800,000 kW over the next five years. This project does not include three small plants of 10,000 kW each, based on atomic energy, which are being built as an experiment; however, no final decision has yet been reached as to the countries where they will be installed.

The Canadian company operating in Mexico which provides some 25 per cent of the total public service capacity (490,000 kW) has drawn up a vast plan for expansion during the next ten years, for a value of 6 billion pesos (approximately 480 million dollars).

Finally, the foreign company established in Bolivia is providing almost the only relief of the critical situation of the country's electricity supply, since most of the financial resources available for energy had to be devoted to the development of petroleum production.

The remaining investment in electricity plants in Latin America—4 per cent of the total—was made by domestic capital and the small municipalities. Despite the financing difficulties besetting this type of enterprise, the effort in relative terms was not insignificant, since 1.6 million kW had been installed by the end of 1955 and work in progress was equivalent to 12 per cent of this capacity. Examples of the action of private domestic capital may be found in several large towns in Brazil, Chile, Mexico, Venezuela, etc. Perhaps the biggest plant of this kind is in Venezuela; it serves Caracas and continues to keep abreast of the capital's growing demand. Over the last

¹² Subsidiaries of the Institute controlled two-thirds of the plants under construction at the beginning of 1956, which totalled some 270,000 kW. Approximately 30 per cent corresponded to thermo-electric plants which have been planned not only to use coal from the Boyacá and El Valle areas, but to promote the development of production of this fuel, to which interesting future possibilities are attributed.

Source: National information.

^a Includes the following groups of companies: CADE, Italo, Soc. de Electr. de Rosario (transferred to ENDE at the beginning of 1956), SUDAM y Cia., Suizo-Argentina de Electricidad, which in 1955 had, respectively, 657,000; 252,000; 112,000; 18,000; and 11,000 kW of the total indicated for that year.

^b Estimates.

^c This total does not reveal the true rate of construction by these financial groups. On the one hand, it may be seen that the Brazilian company is completing a large programme entailing the addition of over 800,000 kW since 1953. On the other, the American and Foreign Power Company has recently begun substantial new plans to put into service a further 800,000 kW in the countries where it operates, over a period of only five years. Moreover, projects are well advanced for major additions by the concessionaires in Greater Buenos Aires included in the table; and the power company in Lima began hydraulic works at the beginning of 1956 for a 30,000-kW plant. The Mexican company has also announced a programme for the investment of 6 billion pesos (approximately 480 million dollars) during the next ten years. In view of this development and of the investments placed in 1955, this company was credited with the estimated figure shown in the table of 150,000 kW, construction of which was under way or about to begin at the end of the year.

^d This company, which belongs to the Electric Bond and Share Co. in the United States, has plants in eleven Latin American countries (Argentina, Brazil, Chile, Colombia, Costa Rica, Cuba, Ecuador, Guatemala, Mexico, Panama and Venezuela).

five years this plant has installed an additional 130,000 kW, and the production of a further 120,000 kW is about to be undertaken.

Private domestic capital also plays a part, although on a minor scale, in many enterprises financed mainly with public funds, in those with autonomous administration and even in foreign private enterprises, through the stock market. This last system has been successful in Brazil, where private investors have added the equivalent of 20 million dollars since 1949, and in Cuba, where the United States company itself has sold bonds to the public for a total of 6 million dollars. This development is significant because it has gradually aroused public interest in the financing of this branch of the economy.

During 1955, gross investment in the region's petroleum industry amounted to some 685 million dollars; 29 per cent was derived from public funds and the remainder from foreign private capital. Only some 350 million dollars were invested in supplies for Latin America. Public investment absorbed 57 per cent of this new total, and was used for oilfields in Argentina, Bolivia, Brazil, Chile and Mexico, as well as some deposits in Colombia. As a rule these fields had sufficient capital for their most urgent needs, which differed in the various countries. In Argentina and Bolivia, for instance, preference is being given to means of transport, which will allow higher output from reserves already located, some of which are being exploited. On the other hand, Brazil is faced by much difficult prospection work, and in con-

sequence, attention was concentrated on the more direct and immediate economic advantages of refining. Chile is consistently developing all phases of the industry and is intensifying the exploitation of its deposits. The State enterprise in Colombia has been obliged to offset the decline of reserves and is concerned with expanding new deposits. Broadly speaking, most of the investment in 1954-55 was placed in refineries, except in Bolivia.

Private petroleum companies also found conditions more propitious to investment in Latin America. Except for Argentina and Brazil, the producing countries strengthened their policy of increasing the participation of the private companies or studied ways and means of doing so. The principal incentive, however, appears to lie in the nature of the petroleum resources; Venezuela, where such resources are extremely rich, receives more and more foreign capital, while other countries—Colombia, Ecuador and Peru, for example—are unable to achieve a substantial increase in production, although they offer greater legal and fiscal inducements.

The influence of the nature of the resources is evident from the results of the various efforts to expand production, both in countries like Argentina, Bolivia, Brazil, Chile and Mexico, where the State holds the monopoly, and in those where private capital plays a part, as it does in Colombia, Cuba, Ecuador, Peru and Venezuela.

Prospection by Argentine experts has located a large potential source in the north of the country, near the Bolivian frontier, and this discovery has been confirmed

by a United Nations Technical Assistance Mission. By 1958, its utilization will considerably reduce the country's dependence upon imports of crude oil. The problem involved is not so much one of investment for production—which will nevertheless be large—as of the distance to be covered by the pipelines between the deposits and consuming centres. At present, special new plans are being studied for the financing of this exceptionally heavy investment, which will exceed 150 million dollars. The magnitude of the financing problem can best be assessed by recalling that 47 and 45 million dollars were invested in petroleum during 1954 and 1955, respectively.

In 1953, the State enterprise in Bolivia discovered a new oil dome with a high potential at the old Camiri fields, and production has thus been raised sufficiently to leave an exportable surplus.¹³ The Government, encouraged by this development, has passed a law enabling that part of the area where the State agency does not operate to be exploited by private capital. In early 1955, a large United States oil company had already announced plans to invest 40 million dollars.

The Petrobras company in Brazil did not neglect the problem of crude output,¹⁴ but its efforts were inadequate to find a solution. Moreover, substantial capital, which was not available, would have been necessary to meet the country's requirements. The discovery of the Nova Olinda field, near Manaus, in early 1955 may prove important, although to date drillings have proceeded more slowly than was expected and production has not yet begun.

Investment in Colombia's petroleum industry has remained constant over the past few years, and has had to cope with the still considerable difficulty of expanding the resources under exploitation. Despite relatively extensive prospecting, it has not yet been possible to counteract the downturn in production at the two principal oilfields. The deposits known as the Concesión de Mares are worked by a State agency formed in 1951 when the concession reverted to the Government; as this is a very big field, the country is confronted with a major financing problem. To raise investment, the enterprise has sought the collaboration of private capital and has signed an agreement with a United States company for drilling in the Carare area, within the concession, which may represent an investment of 7.5 million dollars in five years.

Good results were obtained in Mexico from the greater efforts to develop crude-oil production. The drilling of 330 additional wells (10 per cent more than in 1954) raised output by 12.4 per cent and increased proven reserves by more than 200 million barrels annually. At the Poza Rica field, a new water-injection system was completed, as well as the expansion of the gas re-injection plant and a unit to double the volume of gas processed. These operations represented an aggregate investment of 246.5 million pesos (19.7 million dollars, approximately).

The Empresa Nacional del Petróleo in Chile knows the extent of the reserves in the oilfields it has been

working for some years in Tierra del Fuego, although prospecting has still to be undertaken elsewhere in the country. Programmes are being carried out which have already resulted in an upswing of production during the past three years. It is expected that by 1960 all domestic needs will be met, excluding those of the export mining companies. This presupposes a production increase at an annual rate of 35 per cent. The necessary capital will be obtained from the exchange saved by substituting domestic output of crude oil and derivatives for imports.¹⁵

Since official resources are insufficient for the intensive development of Chile's petroleum potential, consideration is being given to methods of authorizing the exploitation of oil reserves by third parties in areas not worked by the Empresa Nacional de Petróleo.

As already noted, the results obtained in countries where foreign private capital operates have varied widely. In Colombia such capital accounts for 72 per cent of the annual extraction figure and is rapidly raising its share of investment. Legislation and official policy have always favoured the expansion of such enterprise, and during 1955 this attitude was confirmed by new and more specific regulations, as well as by the allowance of a larger deduction from net taxable profits for exhaustion of the wells.

Drillings in Ecuador were unable to improve the quality of known deposits, although prospecting has been extended to many parts of the country in the past few years. In Peru, despite much drilling, no satisfactory results have yet been achieved in the Sechura district, which was opened to private concessions only two years ago.

In Venezuela, however, production moved steadily upwards. Investment exceeded the level of the previous year and will probably be greater still in 1956, especially as the Government plans to expand the area of concessions, and marked interest has been shown by international petroleum capital.

Transport of crude oil and derivatives has also created some investment problems in Latin America.¹⁶

In Bolivia, an intensive construction programme was carried out, to a value of 23 million dollars,¹⁷ while in Colombia expenditure on this item exceeded 15 millions. About 30 million dollars were spent in Mexico on expanding facilities. In Argentina, where there was little advance in 1955, it is planned to invest some 20 millions over the next two to three years.

Refining of crude completed in 1955 a stage of substantial expansion which had begun two or three years previously, while a second such phase, which will require considerable investment, is now opening.

Early in the year refineries were opened in Argentina which brought capacity level with demand, and large new investments to absorb the future growth of total consumption are being considered. In Brazil, as already

¹⁵ It is planned to invest some 1,650 million pesos (equivalent to about 4.5 million dollars) in the proven oilfields during 1956.

¹⁶ See section 3 above.

¹⁷ The Cochabamba-La Paz pipeline will result in substantial foreign exchange saving, because some of the railway freight revenue had to be converted into foreign currency at the official rate.

¹³ Its value may amount to rather more than 6 million dollars in 1956.

¹⁴ It is proposed to invest 26 million dollars in production of crude during 1956.

noted, priority was given to investment in refining, and in another two years it is hoped that refining capacity will keep pace with consumption. The Presidente Bernardes refinery, inaugurated in 1955 with a daily capacity of 60,000 barrels, had represented an investment of 1,500 million cruzeiros (or approximately 50 million dollars) for Petrobras. These activities are not restricted to fiscal enterprise, and Brazilian private enterprise completed two large refineries in 1954.

On the initiative of a foreign company in Colombia, work began on the installation of a refinery at the port of Mamonal, Cartagena, at the end of the year, also to meet domestic demand. It will have a daily capacity for treating some 26,500 barrels of crude and represents a 30-million-dollar investment. Operations should begin in 1957.

Venezuelan investment in refining, which had provided a capacity higher than the demand, fell off during 1955,¹⁸ and only one small refinery was completed during the year. A contract for the supply of liquid fuels for the electrical industry in the United Kingdom led the British company operating in Venezuela to extend its refineries in that country. This new expansion, together with another effected by the largest company, will, over the next two or three years, provide an additional daily capacity of 170,000 barrels. A plant is also being built at a cost of 36 million dollars to produce 35,000 barrels of aviation spirit, and a further large gas reinjection plant is to be installed.

In Mexico, the Pemex company has aimed at raising its refining capacity in order to keep pace with crude production as well as with the requirements of the domestic market and exports, particularly as regards light products. A plan has been completed for the enlargement of the Atzacapotzalco refinery which will increase capacity from 50,000 to 100,000 barrels a day. The Minatitlán refinery was expanded in 1955, with the completion of the first cracking plant to be installed in Mexico.

9. PLANS FOR DEVELOPING ENERGY RESOURCES

Official intervention in the development of energy production and supply in Latin America found more vigorous expression in new ventures and the progress of existing projects. The existence of integral or partial plans does not imply that action has always been taken, but such projects have served to evaluate and emphasize the magnitude of the problem and to indicate financial, economic, technical and administrative requirements. Since almost all the countries of the region are faced with an acute need to promote production of energy, it is clear that any delay will influence their national economies.

Except in such cases as Mexico's, no Latin American country attained all the targets it had established for the development of the different sources of energy. Although achievements were satisfactory in many countries, in others only relative progress could be noted. Circumstances of various kinds combined to hinder the execution of plans and programmes. Among them were difficulties of a financial nature, particularly foreign exchange

shortages. Defects in the programming of work, delays in supplying equipment, mistimed contracting or failure to integrate the various phases of the same project, were frequently decisive obstacles to the due completion of large-scale undertakings. They were aggravated by other administrative difficulties, such as red tape, and vagueness as to where decisions and responsibilities rested. Delays also arose at times because the lack of complete field studies before the work was begun halted its subsequent progress; or, again, they were caused by the non-existence of draft or final plans for projects where adequate and opportune financing would have been available.

Few of the countries had organic programmes covering the whole energy sector and aiming at the co-ordinated development of the different resources in terms of over-all national requirements. It was more often the case that only tentative steps, of no great importance, had been taken to co-ordinate the various forms of energy. In Argentina, however, the organization of the sector is on a much broader basis.

Petroleum production does not lend itself to very precise planning, since it is based on resources of uncertain evaluation. Hence short-range plans by State bodies and official policy directives have alone provided some general guidance. Prospecting has continued, with varying success in the different countries, but, as a rule, drillings have been insufficient—except in Venezuela—to ensure a future increase in production consistent with the forecasts of demand. The same is true of the volume of petroleum extracted.

Nevertheless, plans to increase refining capacity are being satisfactorily carried out and work on pipelines has not been greatly delayed on the whole, except in the case of Argentina.

In contrast, several countries already possess national plans for electrification, which are at various stages of implementation, while others are at present drawing them up. But in this latter connexion a difficulty should be noted. The number of projects begun or being studied in 1955 was insufficient to permit any rapid acceleration in the rate of construction, and would also be inadequate during the next few years, even if the required capital were available.

In Argentina, the high tension lines have not yet been completed,¹⁹ nor had work begun on other connecting systems. Other projects to improve transmission are also well behind schedule.

In Chile, the Empresa Nacional de Electricidad (Endesa) carried out in 1953-54 the first stage of the work on the National Plan drawn up in 1940, but economic and budgetary obstacles prevented the second stage from being initiated. In 1955, budgeted investment amounted to 3,760 million pesos (8.5 million dollars) but only 3,000 millions (6.8 million dollars) were actually available. The estimated 1956 budget of 8,690 million pesos (17.5 million dollars) had to be reduced to 6,620 (13 million dollars) as a result of exceptional fiscal economies arising out of the Government's anti-inflation

¹⁸ Larger investments are planned for 1956.

¹⁹ The fact that the San Nicolás plant, with a capacity of 300,000 kW, was completed at the beginning of 1956, does not invalidate this statement.

plan. This reduction will affect installations of some 125,000 kW under construction. In real terms the budget approved for 1956 will be slightly larger than that of the previous year, but it is insufficient to solve the whole problem, in view of the work which had to be postponed. On the other hand, the National Plan had assumed that some of the work—178,000 kW and the transmission lines to carry energy generated by Endesa—would be carried out by private enterprise, but it is already clear that this target will not be reached, perhaps because the profit incentive is inadequate. To remedy this situation, the Government plans to modify the existing General Legislation on Electrical Services, especially in regard to the public utility rates. The aim is to ensure a degree of profitability which will provide an inducement for the private investor, and at the same time to place the public services on a better financial basis.

Progress in Mexico surpassed previous years' estimates and plans, and the aggregate capacity of 2 million kilowatts envisaged for 1958 will have been exceeded by mid-1956. Despite this evolution, the rate of growth of new capacity declined, since it rose by only 4.3 per cent in 1954-55 in contrast with an annual average of 9.2 per cent during 1950-55. This was the result of the completion of large electrification projects and the withdrawal from service of out-of-date plants; it does not imply any slackening in the pace of future construction. Estimates show that construction already under way or projected will raise capacity by 1960 to 3 million kilowatts, 50 per cent more than in 1955-56.

The Comisión Federal de Electricidad in Mexico will apparently complete by the anticipated deadline—towards 1960—the first stage of its electricity expansion programme, and studies on a country-wide basis for the next ten years are now being carried out. Investments up to 1963 are estimated at 3,529 million pesos (282 million dollars) and 248 million dollars in foreign exchange for the whole electricity programme; 55 per cent will be derived from public funds and will be mainly the responsibility of the Federal Electricity Commission, while the remainder, except for 4 per cent, will be invested by the two foreign enterprises operating in the country.

Other nations—Brazil and Colombia—have established national electrification plans more recently. Their principal aim is the expansion of electricity services, but the programmes at present lack some of the legal instruments necessary for their integral application.

The National Electrification Plan, presented by the Federal Government of Brazil, is still tabled before Congress. It calls for the creation of an agency to be known as the Centrais Elétricas Brasileiras S.A. (Eletrobras), which will undertake a substantial programme of projected works. To finance the plan, the Federal Government simultaneously submitted a draft bill to set up an Electrification Fund, which became law in August 1954. Under its terms, federal, state and municipal governments will receive 40, 40 and 20 per cent, respectively, of the revenue from the Fund and disbursement will be effected through the Banco Nacional do Desenvolvimento Econômico, where these resources will be concentrated. During 1955, it was estimated that a revenue of 1,966 million cruzeiros (some 43 million dollars) would accrue from the following sources: 1,000 millions, from the product of a uniform tax on electricity established in the Fund

law; 420 millions, from one-fifth of the yield of the federal tax on the remittance of funds abroad; and 546 millions from 40 per cent of the revenue derived in 1954 from the tax on consumption.

While the National Plan is being organized, local electrification programmes have been progressing, some in charge of autonomous bodies financed with public funds—such as the São Francisco Valley enterprise—and others through the States, as in the case of Minas Gerais, Rio Grande do Sul, Espiritu Santo, etc.

Colombia's National Electrification Plan, completed in early 1955, shows that investment of some 75 million dollars annually, including local expenditure, would be required for an annual increase of 11 per cent in installed capacity. The plan was drawn up with the collaboration of the Instituto de Aguas y Fomento Eléctrico. A State-financed agency will perhaps be formed to implement it by providing the bulk of the capital, by establishing autonomous entities or by contributing to the capital formation of the enterprises which exist at present. The plan took into account the institutions already operating in the various areas and the work completed to date has in fact been carried out by these organizations. Of particular importance among them is the Corporación Autónoma del Valle del Cauca, whose programme for multiple hydraulic utilization has already received State funds so that the work can be begun, while efforts are being made to obtain a loan from the International Bank.

The electrification plan of the Corporación Venezolana de Fomento did not advance to any great degree during 1955, but, considering the progress made since 1953 and probable developments in 1956, average expansion will probably fulfil expectations.

The programme of the Instituto Costarricense de Electricidad was delayed in 1955; consequently its main hydro-electric project cannot be completed before 1957. Thermo-electric plants are being used to provide immediate services.

Finally, mention should be made of the efforts undertaken by the Comité de Planificación in Ecuador to put into effect a five-year national electrification plan, drawn up with international technical advice. The plan envisages an acceleration of the rate of installing new capacity, which has been too slow in the past.

10. INSTITUTIONAL DEVELOPMENT

During the course of 1955, a number of developments took place in the institutions dealing with energy throughout the region. New agencies were established, existing institutions were reorganized and legislative action was taken to provide facilities.

A National Energy Commission was created in Nicaragua. The structure of State participation was slightly modified in Argentina. Reorganization of the Instituto de Fomento Eléctrico and the establishment of a National Electricity Commission are planned in Colombia. Chile and other countries are considering the adoption of legislative measures for electricity services, to encourage private enterprise and to increase capacity; a law along similar lines has already been passed in Peru.

In 1955, the activities of official agencies expanded, both as regards the study and formulation of programmes

to improve the utilization of national sources of energy and with respect to State investment in specific projects. Progress was also recorded in studies for integrating the utilization of different types of energy and in prospection for available resources; this is particularly true of petroleum, but it also applies to hydro-electricity and coal. Several countries have sought the advice of experts from international specialized agencies. During the period under review, prospecting for radio-active minerals was begun or intensified in some Latin American countries, and most encouraging results have been obtained in some cases. Brazil, which is considered as one of the countries in the world most richly-endowed in this type of resource, is already working monazite deposits. A small plant for producing natural metallic uranium has recently been completed in Argentina. In several other countries there are proven deposits whose grade and size warrant future commercial exploitation.

These activities have in general been carried out by national atomic energy commissions. A body of this nature has existed in Argentina for several years, while Commissions were set up in Chile and Brazil during 1955. In Brazil, the new entity forms part of the National Research Council which has been concerned with atomic energy since 1951. There are similar plans in Bolivia, Peru and Mexico, based in this last case on an institute which deals with radioactive minerals. These five countries, as well as Cuba, Colombia, Uruguay and Venezuela,

have all signed bilateral agreements with the United States which will enable them to receive equipment²⁰ and to obtain nuclear fuel on a hire basis for purposes of atomic research and the training of personnel; this technical training is of considerable significance for the future and is being given well-merited importance by Latin American Governments.

An outstanding aspect of international co-operation in the sphere of energy was the progress achieved in the bilateral utilization of water resources. For example, an agreement was signed between Paraguay and Brazil to study the hydro-electric possibilities of the Acaray and Monday rivers, which are both tributaries of the Paraná flowing through the territory of Paraguay. Under the terms of the agreement, Brazil will carry out the research work and will collaborate with Paraguay in financing the project.

In addition, the Governments of Bolivia and Peru have undertaken a study on the utilization of the waters of Lake Titicaca through a joint *ad hoc* commission, while Argentina and Uruguay have confirmed their interest in building the necessary works to exploit the hydro-electric potential of the Great Falls on the Uruguay river.

²⁰ It has been announced that the first reactor of this type (5,000 kW) will shortly be installed at a Brazilian research centre. Other Governments are also negotiating to obtain experimental reactors.

Appendix

THE MECHANICAL WOODWORKING INDUSTRIES¹

I. GENERAL CONSIDERATIONS

The mechanical woodworking industries cover a great variety of enterprises from the most primitive hewing and hand sawing of pioneer settlers to the modern sawmills and factories that provide the wood construction materials required by modern industrial civilization. The widespread use of wood manufactures which follows the development of mechanical woodworking industries is a clear indication of improvement in living standards. When these products come from local forests managed under sustained yield principles and are produced by local industries, a solid foundation is provided for continuing economic development and the increasing prosperity and well-being of the people of both the country and region. The following pages provide a general survey of the present situation in Latin America's sawmill, plywood, fibreboard and chipboard industries, with special reference to eleven countries² from which reports have been received.

Forest exploitation in Latin America in the past has not been free from the errors which have brought disaster to the forest cover in many other parts of the world. Among such practices are the creaming of the forest by felling only the species of high commercial value, the destructive cutting, with no regard for regeneration, which in many localities has caused the forest to retreat far from the cities, and the wasteful practice, still widespread, of shifting cultivation. Yet, by and large, these practices have not seriously depleted the region's immense forest capital as a whole, but, considering the forests in use, it is clear that exploitation and shifting cultivation have done considerable damage in many countries. Nevertheless, there are a number of factors which justify an optimistic view of the possibilities for a rapid expansion of the mechanical woodworking industries in Latin America, bringing an ever-growing contribution to the region's rising prosperity.

First and foremost the astonishing growth in forest consciousness must be emphasized, particularly during the last decade. Governments and peoples have come to recognize the importance of their natural heritage, and are taking vigorous steps to preserve it and to use it rationally. Since Latin America is a young and rapidly-developing region, this means that much of the unrestrained destruction of the forests which has accompanied industrialization in the more highly-developed regions can be avoided. The establishment of forestry administrations, training schools and research centres promise more highly-skilled management and greater control over the ways in which the forests will be used. Intensive research into the physical and chemical characteristics of the many species encountered in the tropical hardwood forests points the way to the full utilization of these valuable but heterogeneous resources.

New roads and railways which are being constructed in many parts of Latin America are opening up new areas of forest to all-weather use. In several countries recently-built transport routes have made vast wooded areas accessible for the first time; their exploitation may begin whenever demand conditions warrant.

¹ Contribution to the *Economic Survey of Latin America, 1955*, of the Forestry Division, Food and Agriculture Organization.

² Namely, Argentina, Brazil, Chile, Colombia, Costa Rica, Cuba, Guatemala, Honduras, Mexico, Paraguay, and Peru. It is estimated that these countries, which together possess 92 per cent of Latin America's area of accessible forest, account for 90 per cent of the region's total sawnwood production.

The region's forest wealth is not confined to natural forests. These indeed are unevenly distributed over Latin America and in many countries artificial forests have already been created to replace local deficiencies. Of particular note are Brazil's eucalypts, Chile's insignis pine and Argentina's poplar and poplar-willow, but plantations are not confined to these countries or to these species.

Shortage of capital has been a drawback to logging and to the more rapid development of the mechanical woodworking industries, because the seasonal character of many of these industries requires a relatively high capital investment. As national economies develop and local markets expand the capital requirements can also be met more easily.

Forest administrations in several Latin American countries are faced with the difficult problem of managing lands which, although better suited for timber growing than farming, are periodically destroyed by the practice of shifting cultivation. Land ownership in many forested areas is poorly defined and transitory, ownership boundaries and survey corners are often non-existent, while in many areas occupation and use of the land is by temporary "squatters". It is estimated, for example, that in some Central American countries as many as 67 per cent of all farmers can be classed as squatters, many of them practising shifting cultivation which all too frequently destroys forests and soils while adding little to agricultural production. To improve this situation, these transient cultivators should be integrated as far as possible into the forest economy, using their man-power for logging, charcoal burning, sawmilling, planting, etc., while achieving a simultaneous improvement in their agricultural output.

As existing mechanical woodworking industries are modernized and new ones created, some of the population pressure on the land will be relieved by increasing employment in rural industries. Forestry and the manufacturing enterprises based on forest products are particularly well-suited for farmers freed from the struggle for existence on unproductive forest clearings.

II. THE SAWMILLS

The leading product of Latin American mechanical woodworking industries is sawn hardwood, the output of which is estimated to have exceeded 5 million cubic metres in 1955. This volume was made up of a great number of species; for example, even Cuba, with an annual production of sawnwood from hardwood species slightly over 50,000 cubic metres, utilizes no less than 45 species.

Conifers are usually preferred to hard or broad-leaved woods for building and other purposes, because they are more easily sawn, seasoned, and shaped; they are relatively scarce and localized in Latin America but are estimated to have provided approximately 4.75 million cubic metres of sawnwood in 1955.

The number of sawmills and their average annual output are shown in table I. How these sawmills met the current sawnwood needs of the reporting countries may be seen by comparing their statistics with production, imports, and exports for a few selected years. (See table II.) The net exporting countries appear to be Brazil, Chile, Honduras, Mexico and Paraguay. It is interesting to note, however, that the *per capita* consumption of sawnwood, as reported to FAO, is relatively low in most Latin American countries. The data in table III should be accepted with caution, however, because the information is obviously incomplete for many of the countries. The sawnwood consumption of Paraguay and Peru, for example, may actually be considerably higher than the figures indicate.

^a Excluding countries of Eastern Europe.

^b Excluding countries not listed below.

It is evident that although several of the reporting countries of Latin American export sawnwood, their consumption is much lower than in industrially-developed countries of North America or Europe; in these regions, however, timber scarcities have led to economies in the use of sawnwood and to its replacement by other materials.

The sawmills of the eleven reporting countries are mostly privately-owned and financed by domestic capital; foreign capital apparently plays only a minor role in this industry. Plans for expansion of sawnwood production are reported from Chile, Colombia, Honduras and Mexico. Several of the projects are to be integrated with pulp manufacture and with plants for utilizing sawmill by-products.

1. ARGENTINA

According to the Fourth General Census of Argentina made in 1946, there were a total of 1,009 sawmills. Details about their sizes were not reported. An estimate of employment in sawmilling during 1955 indicates a total of 9,850, of whom 22 per cent were classified as skilled workers.

Sawmills have not been integrated with other woodworking industries and the only major use of their residues is for fuel.

Sawnwood output (see table II) is predominantly of the hardwood species. Sleeper production reported for 1953 reached 90,000 cubic metres and increased to 99,000 in 1954. It is estimated that less than one-fourth of the railway sleepers are treated against decay. Argentina is a net importer of sawnwood, the main sources of imports being Brazil, Chile, Romania, Paraguay, Poland and the United States.

According to the 1953 world forest inventory, Argentina then had 10 million hectares of forests in use, while 50 million hectares of accessible forest land remained to be developed. For the most part these resources are far from the main population centres, but in recent years extensive stands of poplar, willow and pine species have been planted in the Paraná delta area. Plans existed in 1955 to modernize and to expand the sawmill industry on a moderate scale.

2. BRAZIL

The total of 5,484 operating sawmills reported in Brazil (see table I) refers to the four southern States of São Paulo, Paraná, Santa Catarina, and Rio Grande do Sul, data for the rest of Brazil not being available. These mills are mostly small enterprises and many are equipped with single-unit frame head saws.³ Some

³ Four types of head saws were reported in Latin America: circular, band, gang, and frame. Circular saws are the most common and, although well adapted to small mills, particularly portable and semi-portable types, they cut a wide kerf and are therefore relatively wasteful. Band saws, like circular saws, are used

10 per cent are band sawmills and 25 per cent have gang head saws. Approximately 10 per cent of the total number of sawmills are electrically-driven, the rest being steam-powered. The workers are mostly unskilled, only one-tenth being classified in the "skilled" category.

Integration with other woodworking industries has shown little progress to date in Brazil. The only significant utilization of sawmill residues is for fuelwood.

Brazilian sawmills are located mostly near the forests. Their record of stability of operation is relatively good, for example, in 1955 only 18 sawmills were reported idle and 5,484 were operating. The chief cause of idleness was said to be the lack of raw materials available to individual mills.

Brazilian sawnwood output (see table II) is 70 per cent Paraná pine (*Araucaria angustifolia*), the only important softwood species.

Sawnwood exports (almost entirely Paraná pine) during 1953 and 1954 were mainly shipped to Argentina, the United Kingdom, Uruguay, the Union of South Africa and Western Germany. Small tonnages have also been exported to several other countries, primarily in Europe and North America. Sleeper exports totalled 14,000 cubic metres in 1953 and dropped to 5,300 in 1954.

There is a strong overseas demand for Paraná pine, but fears have been expressed that the accessible forests of this species have been excessively exploited in the past. The regeneration of Paraná pine presents a number of difficulties, but in recent years efforts have been made to establish plantations. Meanwhile, domestic demand for sawnwood is growing swiftly. A rapid rise in population and a high building rate call for an increasing volume of sawnwood. One of Brazil's important resources is the extensive plantation area of eucalypt, especially in the State of São Paulo. The planting of eucalypts started at the turn of the century and was originally designed to provide fuel for wood-burning locomotives.

3. CHILE

The outstanding success of Chilean plantations of coniferous species is reflected in the increasing output of soft sawnwood. (See table II). The total of 472 sawmills (see table I) includes 450 within circular headsaws, an unusually high proportion for Latin America. Of the non-circular headsaws reported, 20 are band saws and 2 are gang saws. The circular mills are steam-powered whereas the others use diesel engines. About 90 per cent of the sawmill workers in Chile are listed as relatively unskilled, as may be expected where the mills are small.

The sawmill residues are used chiefly for fuel, either to supply steam power to the mill or as household fuel. Some slabs, edgings, and trimmings, however, are made into boxboards, parquets, broom handles and roofing material.

Chilean sawmills are nearly all conveniently close to forests, either in the forest itself or in nearby small communities. Only three of the sawmills reported in 1955 were government-financed, the rest were privately-owned and investment capital reportedly came from Chilean sources. A new mill financed by French capital is now being installed. The sawmills provide employment to over 10,000 persons annually.

Sleepers are mostly hewn rather than sawn, and annual production in recent years has averaged slightly over 100,000 cubic

where "sawing for grade" is desired. Logs can be turned between each cut so that the maximum quality can be extracted from each log. Band saws cut narrower kerfs than circular saws but are usually less easily portable. Gang saws make multiple cuts simultaneously and thus have a relatively high volume of output but little opportunity for obtaining high-quality yields. The frame saws which were reported had single blades supported in frames which oscillate to give the cutting action. Frame saws tend to give a low yield in both quantity and quality, but they have the advantage of easier maintenance and operation—qualities which are desirable where sawmill technicians are scarce.

metres. Only 10 per cent of the railway sleepers currently used in Chile are treated with preservatives.

The mainstay of the softwood output is the planted exotic Monterey pine (*Pinus radiata*). In 1954, about 186,000 hectares were planted with this species from a total area of forest plantations exceeding 300,000 hectares.

Although a net exporter, Chile imports a small volume of sawnwood from the United States. Exports have been principally shipped to Argentina, various other South American countries, the United Kingdom and Australia. Most of the exports go to Argentina, having been stimulated by the trade agreement signed in 1954.

The outlook for the sawmill industry of Chile appears to be favourable for further modernization and expansion. Plans exist for the development of an integrated woodworking plant for utilizing native hardwoods, while construction is progressing on another integrated sawmill. A large sawmill to produce wood for the North American market is also planned. The integrated production of soft sawnwood and pulp is contemplated in factories now in the installation stage.

Although many sawmills are still operating with worn-out and antiquated equipment, much has been done to improve manufacturing facilities and new sawmill machinery is being imported. As the equipment is improved and modernized, manufacturing and export will expand. Furthermore, timber supplies will increase as new plantations become productive.

Progress in forestry and forest industries will undoubtedly be stimulated by the training facilities now available in Chile. This programme, a joint achievement of the Government of Chile and FAO, combines professional training in forestry with practical training and experience in modern sawmilling.

4. COLOMBIA

Most of the 150 sawmills reported in Colombia are small diesel-powered circular rigs. (See table I.) Only 30 mills are still steam-powered, indicating that a certain degree of modernization has taken place. The Colombian sawmill industry, on the other hand, employs more workers per operating plant (67) than in any other reporting country except Honduras (90). Aggregate employment in this activity in Colombia was estimated to be 10,000 persons in 1955.

Most mills are located in or near the forest areas and operate under conditions which provide little opportunity for integration with processors of the various by-products. Sawnmill residues are usually wasted, only about 10 per cent being used for fuel.

Private ownership and local financing are characteristics of the Colombian mills. An unusually large proportion of sawnwood output comes from primitive handsawing, production from this source representing about 225,000 cubic metres in 1954. This may be compared with a total sawnwood output of 670,000 cubic metres.

Colombia is currently a net exporter of sawnwood, although the volume of the shipments is relatively small.

The outlook for further development in the sawmill industry is extremely favourable. According to the FAO World Forest Inventory of 1953, less than 1 per cent of the 62 million hectares of accessible forest land is at present exploited. The per capita consumption of sawnwood is very low (see table III) and can be expected to increase. The lengthy mileage of navigable waterways facilitates the transport of both logs and sawn products. Plans and development work are progressing on new integrated manufacturing plants, including factories for production of sawnwood, plywood, fibreboard, and pulp.

5. COSTA RICA

The sawmills of Costa Rica are almost all small in size (see table I) but show a varied range of saws and motive power. From a total of 168 sawmills, 100 have circular head saws, 54 are

equipped with band saws and 14 are gang sawmills. As to type of power 58 are diesel mills, 64 water-powered, 39 electric, and 7 are driven by petrol engines.

About 70 per cent of the sawmill residue is utilized as fuel; this high consumption is attained because 85 per cent of the mills are located in or near towns and cities. Only one of the mills is a State-financed operation, the remainder are owned and financed by private enterprise in Costa Rica. Sawmill industry employment was reported at an annual average of over 1,300 workers and, in addition, local hand-sawing provides some small additional employment. Foreign trade in sawnwood is negligible in volume.

As an active participant in the Economic Integration Programme of the Central American Republics, Costa Rica can expect to benefit from the general development of production and trade which will probably be accelerated by closed co-operation between the countries, exchange of technical skills, and modernization of industry. The various international organizations are assisting Costa Rica, as well as its neighbouring countries, to improve forest management and the woodworking industries. The training centre at Turrialba, Costa Rica, is providing local facilities for technical training, including various aspects of forestry.

6. CUBA

With one of the smallest forest areas per inhabitant of any country in Latin America (0.2 hectares), Cuba is a net importer of sawnwood. Nevertheless, the 1,090,000 hectares of forests in use provide raw materials for 235 sawmills (see table I) which recorded a production in 1954 of 53,000 cubic metres. This output represents but a very small fraction of aggregate Cuban capacity. Sawmills have been established in the past with complete neglect of the sustained yield possibilities in the areas exploited. Even so, Cuba's forest resources are insufficient to maintain a reasonable rate of output in all the existing sawmills. Sawnwood imports in 1954 were estimated at 159,000 cubic metres, while sleeper output stood at 23,000.

The Cuban mills are almost all steam-powered. Nearly two-thirds of the head saws are band saws, the rest being circular. One-fourth of the employees were classified as skilled workers.

Most of the Cuban mills are in or near towns and a ready outlet is thus available for residue from the mill. Thus all sawmill "waste" is used as fuel.

Minor tonnages of special sawnwood grades are exported to the United States and the United Kingdom. Sawnwood imports come from Brazil, Chile, France, Japan, Mexico, Spain, Surinam, the United States and Western Germany.

7. GUATEMALA

With a wooded area per inhabitant close to that of the United States, more than half of Guatemala's forests remain inaccessible. The 78 sawmills reported operating in 1955 were mostly small, diesel and electric-powered, and equipped with circular saws. The estimated average annual sawnwood output for recent years is about 180,000 cubic metres. In addition, a few sleepers are produced, the estimated output being only 740 cubic metres in 1955.

Sawmills are generally located in towns or cities and only 8 of the total are in the forests. A relatively small tonnage of the sawmill residue is utilized, however, for fuel.

Sawnwood exports, which stood at 6,400 cubic metres in 1954, were mostly shipped to British Honduras, El Salvador, the United States and Western Germany.

Guatemala has excellent prospects for the further development of forest management and for the modernization and extension of forest industries. Contributing to this favourable outlook is the fact that much interest is being shown in improving technical skills for both forestry and lumbering. Several international organizations are co-operating with the Government of Guatemala

to improve forest management and exploitation. Plans have been made and action taken to improve logging and sawmill machinery, which will tend to increase both the quality and quantity of sawnwood output.

8. HONDURAS

With an unexploited but accessible forest area of about 2 million hectares, composed of both coniferous and broad-leaved species, Honduras is particularly well favoured to maintain and expand its mechanical woodworking industries. A total of 67 sawmills were operating in 1955 (see table I), while 14 were idle due to financial difficulties or lack of raw materials. The sawmills are, on the average, larger than those of most other reporting countries. Sixty-two mills in operation reported circular head saws and 5 were equipped with band saws. As to motive power, 32 were steam-driven, 33 diesel and 2 electric-powered mills. In 1955, the estimated employment in the industry stood around 6,000 persons, of whom 10 per cent were classified as skilled workers. Honduras also has a hand-sawing industry producing approximately 10,000 cubic metres of sawnwood each year. Annual output of hewn sleepers averages about 20,000 cubic metres, nearly all of which are treated to preserve them.

Most of the sawmills in Honduras are located in or near forests, although 20 are in cities and towns away from forested areas and 7 are export centres. Ownership is private in nearly all cases, with 7 closely connected to the two large fruit-growing enterprises. It is estimated that foreign sources provide three-quarters of the capital for the sawmill industry.

Honduras exports its sawnwood principally to Cuba, El Salvador, the United States and Venezuela.

Considerable progress may be anticipated in the mechanical woodworking industries as a result of the favourable locations and terrain and of the valuable species in the large area of unexploited forest. Honduras is strategically located at the centre of the Central American isthmus and thus has ready access to export markets by sea and land. Further development of the forests within the framework of the Central American Economic Integration Programme may be expected. Domestic consumption of sawnwood, already at 160 kilogrammes per inhabitant (see table III), is expected to increase as a result of expansion in building construction. It is also believed that the export prospects for sawnwood are capable of further development. The opening of new roads in northern Honduras and greater imports of machinery and fuel will assist in the exploitations of new forest areas and the installation and modernization of the present sawmills.

9. MEXICO

The sawmill industry has not shared in the rapid industrial growth that is generally taking place in Mexico. Industrial production as a whole has doubled since 1951, but sawnwood output declined from 1,420,000 cubic metres in 1951 to 940,000 in 1954. This decrease is not due to lack of forests but rather to their location in relation to the consuming centres. Over 20 million hectares of forest are reported as accessible but only 4.5 million hectares are actually being exploited. The forest policy of the Government has been to reduce production in exhausted areas; timber-cutting permits have thus been cancelled in many public forests. The regulations provide for studies to determine forest yields and up-to-date methods must be used by those exploiting public forests, so that the maximum yield from operating sawmills may be fostered. The transfer of sawmills from over-cut areas is also encouraged. The opening up of new forests has not kept pace with the rationalization of exploitation in the traditional areas and total production has thus suffered.

Approximately 300 sawmills were active in Mexico during 1955. Only one of these mills was equipped with a gang saw, 12 per cent had circular saws and the remainder used head saws. Steam is the most common form of motive power.

The sawmills in Mexico are usually located in or near the forests which supply the wood. In some forests, particularly in the Yucatán territory, integrated industries are being developed; plywood plants and furniture factories supplement the sawmills and thereby permit the forest raw materials to be utilized more fully and rationally. The trade in sawnwood is primarily with the United States.

Sleeper production in Mexico was reported at 256,000 cubic metres in 1953 and 367,000 in 1954. Output in 1953 included 120,000 cubic metres of hewn sleepers, the remainder being sawn. No breakdown of the 1954 output is at present available.

The outlook for the development of the sawmill industry in Mexico is excellent. Large areas of valuable coniferous and broad-leaved species await exploitation and the expressed policy of the Government is to secure their use under rules of operation which will seek to maintain the forests as a growing source for a permanent wood supply. In 1954, sixty-three State-owned nurseries produced 36,750 million seedlings. The widespread interest in forestry is noteworthy.

10. PARAGUAY

With 4.3 hectares of accessible forest per inhabitant, Paraguay is more favourably endowed in this respect than any European country except Finland (5.1 hectares) and is ahead of all the other reporting countries in Latin America except Colombia (5.2 hectares). An estimate for 1953 suggests that about half the value and three-quarters of the tonnage of annual exports from Paraguay were made up of forest products. Yet the current survey shows that the sawmill industry is far from flourishing, since 57 mills were in production and 13 were not operating. The causes for this high rate of idleness were given as inadequate capital and lack of markets. Sawnwood consumption in Paraguay is the lowest reported in Latin America.

Most of the sawmills are of small size (see table I) and use steam-powered band saws. Of the 57 mills only 2 had circular headsaws, 29 had band saws, and the remaining 26 were gang mills. The motive power was classified as 49 steam, 2 steam-electric, 1 diesel-electric and 5 petrol-driven. Employment in the sawmill industry was reported to be 850 workers, of whom about a quarter were listed as "skilled" in 1955.

One of the sawmills in Paraguay is integrated with a plywood factory. The utilization of waste, mostly as fuel, is reported to be excellent for the entire industry.

Sawnwood output (see table II) was about 120,000 cubic metres in 1952. Most of this volume was produced by sawmills, but approximately 4,000 cubic metres annually are estimated to come from primitive hand-sawing operations. Sleeper production in 1953 stood at 5,000 cubic metres. Forest and forest products statistics are not sufficiently well developed to give accurate or up-to-date information.

The forests of Paraguay are all classified in the broad-leaved group and no coniferous forests or softwood production are known.

Sawnwood exports represented 19,000 cubic metres in 1953 and 13,000 in 1954. About 95 per cent of these exports were dispatched to Argentina, with which country a trade agreement exists, and the remainder went to Uruguay.

The outlook for increased sawmill production is difficult to assess because it is dependent upon the domestic economic situation. A large area of accessible forest remains unexploited (over 1.25 million hectares), but sawnwood consumption is so low that some increase in domestic requirements may be expected.

11. PERU

A very low level of sawnwood consumption (see table III) and relatively little progress in forest exploitation characterizes the situation in Peru. The 95 sawmills reported as operating in 1955

were almost all very small (see table I), but had a variety of power plants. The most common source of power was the petrol engine, reported at 36 sawmills. Other forms of energy listed were as follows: 29 diesel; 17 steam; 8 electric; and 5 water-driven. The types of head saw reported were: gang, 44; circular, 43; and band saws, 8.

In addition to a sawnwood production of 77,000 and 86,000 cubic metres in 1953 and 1954 (see table II), the woodworking industries of Peru showed a sleeper output of 14,000 and 22,000 cubic metres, respectively, during these years. The hand-sawing industry is small, averaging only about 3,000 cubic metres of sawnwood annually. The estimated employment in the whole industry stood at 3,000 workers in 1955.

The sawmills are located for the most in or near the forests, usually along navigable rivers. Only 3 of the 95 sawmills are State-owned, the rest are private enterprises mainly financed by Peruvian capital.

Peru is a net importer of sawnwood, mostly softwoods. Imports arrive chiefly from Argentina, Canada, Ecuador, Nicaragua, the United Kingdom, the United States, and Western Germany. Small tonnages of broad-leaved sawnwood are exported to Argentina, Bolivia, Cuba, Spain, the United Kingdom and the United States.

The future development of the sawmill industry depends to a considerable degree on the general economic growth of Peru. Government policy has encouraged imports of machinery, particularly for agriculture, which may have favourable effects on the sawmill industry. The intensified campaign to colonize some of the forested zones may serve to open up new rural and forested areas and to increase sawnwood utilization.

12. OTHER COUNTRIES

Although the non-reporting countries produce only about 10 per cent of the region's aggregate sawnwood, this output is important to the individual countries. It is also probable that the sawmill industries of several of these countries may expand in the future. For example, the Forest Service of Bolivia recently imported logging equipment and domestic sawnwood production in recent years has reached substantial tonnages. The establishment of several sawmills of medium capacity (20 to 80 cubic metres daily) was reported almost ten years ago.

British Guiana had 76 sawmills and 40 saw pits operating in 1954. The sawnwood production (including sleepers) stood at 183,000 cubic metres in 1953 and 83,000 in 1954.

British Honduras reported 21 sawmills in 1954, with a production of 51,000 and 45,000 cubic metres in 1953 and 1954, respectively. The sawnwood output of the Dominican Republic is noteworthy, representing 64,000 and 56,000 cubic metres for 1953 and 1954. Ecuador at present produces relatively little sawnwood (29,000 cubic metres in 1953) but possesses large resources of virgin forest. Two million of its 2.5 million hectares of accessible forest remain unexploited, while an additional 9.5 million hectares of forest are classified as currently inaccessible.

Heavily-forested French Guiana has recently established a Forestry and Agricultural Office to encourage forest industries by facilitating loans, providing equipment and carrying out market studies. Nicaragua reports sawnwood exports of 86,000 cubic metres in 1953 and 60,000 in 1954, which suggests a sizeable output, even if production statistics are not available. According to a report prepared in 1948, a total of 56 sawmills were operating in Nicaragua at that time.

With an area of only 235,000 hectares of accessible forest, Trinidad and Tobago nevertheless had 70 operating sawmills in 1954, including 21 band mills. Factories for matches and boxes also were in production.

Two other fairly important producers of sawnwood, Uruguay and Venezuela, must be mentioned. Uruguay reported an output of 51,000 cubic metres for 1954 and Venezuela produced 110,000 cubic metres in the same year.

III. THE PLYWOOD INDUSTRY

Plywood (including blockboards) has been produced in several of the Latin American countries for a number of years. The output of the two leading producers, Argentina and Brazil, has varied considerably from year to year; aggregate production in Latin America has grown from 150,000 cubic metres in 1946 to an estimated 205,000 in 1955.

The steady growth of plywood production and utilization is being encouraged by the advances in plywood technology. Improvements in glues have allowed the product to be used both indoors and outside, as well as for a variety of purposes. Many Latin American woods have colour and grain characteristics which make them particularly suitable for decorative plywood; much of the region's output is made into furniture.

1. ARGENTINA

The plywood industry of Argentina has received special official encouragement by being declared an industry "of national interest". Nevertheless, from a total of 49 plywood plants only 28 were in operation during 1954. Argentina's plywood industry was established many years ago and has since expanded somewhat beyond the availability of domestic raw materials.

As indicated in table IV, the plants are mostly small in size. In spite of the many mills which were not operating, the 1954 output reached 31,000 cubic metres and for 1955 it was estimated to stand at 35,000. (See table V.) The industry is estimated to have employed 1,635 persons in 1955.

Table IV. Latin America: Plywood plants

^a 90 per cent were reported in this category.

^b Other plants were reported in Bolivia, Guatemala, Surinam and Venezuela.

Plywood is used in Argentina for the manufacture of furniture, for crating and for interior panelling. Domestic production usually falls short of requirements and imports are necessary from Brazil, Finland, Sweden and the United States. The outlook for any appreciable increase in domestic production is unfavourable because raw materials for existing domestic plants are in short supply.

2. BRAZIL

The leading plywood producer, Brazil, accounts for about one-half of Latin America's output. The 234 plants listed in table IV are in the southern States of São Paulo, Paraná, Santa Catarina and Rio Grande do Sul. Rotary peeling is accomplished by 180 of the mills and 54 produce sliced veneers. The factories are nearly all located in centres of population. They produce for domestic consumption, since exports, which were substantial in the early post-war years, are now negligible. Financing appears to come almost entirely from Brazilian sources.

The bulk of plywood output is from Paraná pine (*Araucaria angustifolia*), though some hardwood species are used. Plywood output is used primarily for furniture (70 per cent), crating and interior panelling.

Table V. Latin America: Plywood production and exports
(Thousands of cubic metres)

^a FAO estimates.

The outlook for the Brazilian industry is optimistic because domestic markets are expanding with over-all economic development and the increase in population. It seems probable that raw materials will be available to permit the expected expansion. The export market situation, however, remains somewhat unfavourable; one reason is the general expansion of plywood production in the countries which formerly received Brazilian exports.

3. CHILE

Chile is the fourth largest plywood manufacturer in Latin America and, with a 1954 output of 13,000 cubic metres, ranks behind Brazil, Argentina and Mexico, in that order. Only 4 plywood plants are reported (see table V). Three are rotary peeling plants and one produces sliced veneers. Three of the plants are located in or near the forests, while one is situated at a port and utilizes domestic and imported logs. All the factories are a considerable distance from Santiago where 70 per cent of the domestic plywood is consumed.

The factories are all privately owned and are financed by either Chilean or Argentine capital. Some expansion and modernization is at present proceeding, including, for example, the installation of new machinery from Western Germany.

An estimate of the present use of plywood shows 50 per cent for flush doors, 40 per cent for furniture and 10 per cent for construction, building interiors and exteriors, railway carriages, boats and aeroplanes.

Foreign trade is currently of minor importance with exports slightly exceeding imports. Small exports are made to Peru, the United Kingdom, Venezuela and some other South American countries.

Plywood production in Chile will increase as domestic consumption rises. The present consumption is estimated at 1.1 kilograms per inhabitant, in contrast with an average of 2.9 for Europe and 16.6 for North America, for example.

4. COLOMBIA

Colombia produced an estimated 6,000 cubic metres of plywood in 1954 from 3 plants which are all equipped for rotary peeling. They are all privately owned and financed with domestic capital; the factories are located in cities some distance from their wood supplies. Average annual employment is estimated at 300 persons.

All the plywood output is used within Colombia and small tonnage is imported. Approximately 60 per cent of plywood used is

for interior finishing and doors, about 20 per cent for furniture and the remaining 20 per cent for miscellaneous uses. Imports mainly come from the Netherlands, the Netherlands West Indies, Panama, Surinam and the United States.

Prospects for continued expansion in the domestic market are good, with a 30 per cent increase in the anticipated plywood needs arising from existing building programmes. No expansion of plywood exports is foreseen, however, because the output of the present factories that are under construction at Tumaco and a further plant in the blue-print stage, will all be absorbed by the domestic market.

5. HONDURAS

The one plant operating in Honduras employs about 50 workers and in 1954 produced about 7,000 cubic metres of plywood. Domestic consumption is expected to expand in the near future and the prospects of exports to neighbouring Central American countries are favourable.

6. MEXICO

An annual output of about 20,000 cubic metres places Mexico in third place as a regional producer of plywood. One of the factories is at Mexico City, the remaining 4 are near or in the forest area. The species used are principally pine, mahogany and cedar. Some plywood is imported from the United States and a small export market is supplied in Cuba, the United States, and Porto Rico. Domestic use of plywood is chiefly for furniture and doors.

Further expansion in production may be expected in view of the over-all economic development of Mexico and the ready availability of veneer logs from various species. New plywood mills are planned for Quintana Roo in south-east Mexico, using mainly mahogany, and for Chihuahua in the north, using pine.

7. PARAGUAY

The two plywood plants in Paraguay produce both rotary cut and sliced veneers for the domestic market. About 200 persons are employed and the annual output is close to 2,000 cubic metres. (See table V.)

According to recent estimates, 80 per cent of the product is used for crating and the remainder supplies furniture factories.

8. OTHER COUNTRIES

Plywood mills have been reported as operating in Bolivia, Guatemala, Panama, Peru, Surinam and Venezuela.

The factory in Bolivia has apparently produced mainly citrus-crate veneer, but recent information is lacking. Plywood has been manufactured in Guatemala since 1950 and the output was estimated at 7,000 cubic metres in 1954.

Panama has had an operating plywood plant since 1953, with an annual output of about 3,500 cubic metres. The species used include *Anacardium excelsum*, *Bombacopsis quinata*, *Calophyllum rekol*, *Copaifera chiriquensis*, *Prioria copaifera* and *Swietenia macrophylla*.

Peru reports two plants operating in 1955, which employ about 60 workers. Surinam had a 1954 production of 10,000 cubic metres, but details of the factories are unavailable. An output of 3,000 cubic metres of plywood was reported by Venezuela for 1953, but once again details are not at present to hand.

Broadly speaking, the prospects for Latin America anticipate further growth in plywood production to keep pace with the demand arising from current economic and social development.

IV. THE FIBREBOARD AND CHIPBOARD INDUSTRY

A robust newcomer to the family of forest industries is the manufacture of fibreboards and chipboards. The former product is essentially a result of a pulping process whereby wood fibres are separated, formed into a mat—with or without the aid of water—and pressed into sheets held together by the felting of the fibres or by the natural lignins, added resins or other materials acting as binders. Fibreboard is usually classified into the two groups of hardboard and insulating board; the latter is defined as material, usually from 8 to 20 millimetres in thickness, with porous structure and with good thermal and acoustic insulating properties. Chipboards, which are not products of pulping processes, are made by breaking up wood into small pieces—such as chips, shavings, or sawdust—and forming them into sheets, with resin binding agents fused by heat and pressure. Both fibreboards and chipboards are finding increasing uses as building materials, especially where low cost and insulation against heat and sound are important. To some extent fibreboards are replacing plywood in packaging, furniture manufacturing and the interior finishing of vehicles and buildings.

Fibreboard and chipboard can be manufactured from a great variety of materials, the factories can be established with less capital than pulp and paper mills, for example, and a demand exists or can easily be fostered in nearly all the countries. Latin American fibreboard production dates back only to around the year 1950, when the first plant was opened in Argentina. Two years later a factory in Brazil entered operation. Since then, another plant has been installed in Brazil and a fourth was established in Mexico. A chipboard plant is also now operating in Colombia.

The plant in Argentina, using the Asplund defibrating process, has an annual capacity of 4 million square metres of 3.5 to 5 millimetres thick board. The estimated output of hardboard for the year ending 30 June 1955 was about 16,000 tons mostly from eucalypts, although casuarina and willow are also used.

The Argentine fibreboard plant employed 320 workers in 1955 and, because the industry is new and demand for its product is increasing, it may be expected that both employment and output will expand. Fibreboard in Argentina is used for interior finishing and furniture; the entire current and prospective output will probably be absorbed by the domestic market.

The estimated 1955 production of the two Brazilian factories is 4,200 tons of hardboard and 6,000 of insulating board. They are mainly used for building interiors and for furniture. In contrast to the development of the fibreboard industry in Argentina, where the aim is to produce for the domestic market alone, the plants in Brazil are expanding in order to enter the export market. Small shipments have been made to the United Kingdom, the United States and Western Germany. The industry looks to the

Government for assistance in its trade problems, especially as regards equipment imports.

No fibreboard plants are yet reported from Chile, although the importation of "wallboard" manufacturing equipment from the United States was authorized by the Government in 1953. In the meantime, machinery has been imported from Western Germany for a plant with an annual capacity of 10,000 tons, which is to begin operations in 1956 using *Pinus radiata* as a raw material. Fibreboard is imported into Chile from the Netherlands, the United Kingdom and the United States. The domestic demand for fibreboard, for crating and building interiors, may be expected to improve when local supplies at lower prices become available. The main prospective export market is in Argentina.

Colombia has one operating chipboard factory, a fibreboard plant is under construction and plans have been drawn up for an integrated paper pulp, hardboard, plywood and sawnwood mill in the Magdalena River valley. The existing chipboard plant employs about 25 workers and 1954 output stood at 1,800 tons.

This factory is well located with respect to markets for its product, but raw materials are not readily accessible. Various tropical species of wood are utilized. The expansion of manufacturing facilities taking place at present is expected to supply the domestic market and leave a balance for export. Hardboard is currently imported from Canada, Sweden and the United States, the volume reaching 1,500 tons in 1954. About three-quarters of the hardboard and chipboard consumption is for interior finishing.

One fibreboard factory exists in Mexico, which has been operating since 1950, the raw material coming from some 34 tropical species, most of which are of low quality for timber use. With a capacity of 12,000 tons per year, the estimated 1954 output reached 10,000 tons. The output is entirely of hardboard and a large part of it is exported. The main export destination to date has been the United States with smaller volumes to El Salvador and Peru.

The possibilities of further development in fibreboard and chipboard plants in Latin America are extremely favourable. As already pointed out, investment costs are relatively low, apparently almost all indigenous and exotic softwood and hardwood species can be used and every country has an active or latent demand for the products.

V. CONCLUSIONS

This short review of the current situation of the mechanical woodworking industries in Latin America is necessarily brief and incomplete. Over most of the region, statistics for forest industries and their output are still in an elementary stage. Even in highly-developed regions, the task of collecting data on small and scattered sawmills, for example, is far from easy. For the most part, the figures which have been quoted in the preceding pages represent informed estimates by those closely associated with the industry in the countries concerned. It is clear, however, that in most Latin American countries small-scale operations predominate; large units with up-to-date equipment are exceptional, being confined to areas where either a significant domestic demand has grown up or an extensive export trade has been developed. In some countries, thoughtless exploitation of the forests has gone hand in hand with over-development of the sawmilling industry, from the aspect of a continuity of raw material supply. In others, sawmills and plywood plants have encountered difficulties arising, not from any over-all lack of raw materials, but from the increasing distance of the raw material sources as forests have been driven back from urban areas. Lack of developed communications has hampered both the acquisition of raw materials and the shipment of wood products to consuming centres.

The region as a whole continues to be dependent on imported wood products to an extent that is hardly consonant with the region's vast forest wealth. Moreover, having regard to the complementary nature of these resources as between different coun-

tries and areas in Latin America, it is surprising that intra-regional trade is not more highly developed.

In recent years plywood technology has made rapid strides in Europe and North America, multiplying and diversifying the applications of this forest product. These findings must still be applied in Latin America and potential new markets have yet to be created. Similarly, the fibreboard and chipboard industries are still in their infancy; though neither of these industries call for heavy capital investment, both can operate successfully on a wide range of raw materials and both yield products of a variety capable of calling new markets into existence at once. Efforts are being made in a number of countries to modernize the existing sawmill industries. These attempts must be intensified and extended to other countries if the region's mechanical woodworking

industries are to make their potential contribution to the over-all economic development now taking place throughout Latin America. At the same time investment in the younger branches of the mechanical woodworking industries would appear to offer prospects of a considerable saving in foreign exchange and to safeguard, through integration, the economic operation of existing forest industries.

Co-ordination within the region of national development plans for forest industries seems eminently desirable. Thus the efforts which are being made to ensure a well-balanced development in Central America will continue to be regarded with great interest. The success of this programme is bound to provide a stimulus for similar co-ordinated action on the part of neighbouring countries elsewhere in Latin America.

Part II

**GOVERNMENT INCOME AND EXPENDITURE
1947-1954**

INTRODUCTION

One of the most important economic developments of this century, and in particular of the last twenty-five years, has been the utilization of fiscal policy for the attainment of ever-broader objectives of economic and social policy. In contrast to the more orthodox public finance of the nineteenth century, which aimed at the lowest possible level of State expenditure and at minimum interference by the official sector in the free play of private interests, more recent decades are characterized by active State participation in the economy with a view to weakening violent cyclical fluctuations, maintaining the level of employment and, more recently, promoting the growth of income, correcting maladjustments in certain parts of the economic mechanism and even producing a distribution of the national income more in harmony with present social ideals. Logically this amplification of the public sector's functions has been accompanied by a formidable increase in State expenditure, in the tax burden and in the public debt, all of which are general characteristics of the fiscal structure to-day in all the countries of the world and particularly in those which are highly industrialized.

The outstanding trends of the world economy were reflected from the very beginning in Latin America. One after another, almost all the countries in the region have in recent decades carried out taxation and fiscal reforms designed to modernize former systems and to provide Governments with the resources needed for their ever-growing functions. Simultaneously, activities of an economic and social nature have been increasing their share of public expenditure, until they have come to form a very substantial proportion of State budgets. This process is still at what might be termed its "formative stage". Broadly speaking, modifications and reforms in taxation systems and the structure of expenditure have not been established in accordance with plans previously formulated for long-term requirements, but rather have been carried out as emergency measures to meet changing conditions in the economy or in social policy. Hence it is not uncommon to find many countries where, alongside undoubted technical advances and well-conceived systems for the administration of certain taxes, specific laws and anachronisms weaken the economic use of fiscal policy.

The main reason for the new trends in Latin America's fiscal policy has been, and continues to be, that the State must now play an active role in the promotion of economic development. Development policy is nothing new in the Latin American environment, since it has been a concern of Governments for many decades; nevertheless, the current conditions for this process oblige the public sector to assume new responsibilities and to carry out tasks which in other regions and at other times were in the hands of private enterprise. In this case it is not a question of a political or social ideology, but of the evolution over a long period of a series of concrete decisions which have had to be reconciled with real existing conditions. As a result, in recent years a firmer

criterion of the need for economic development has been established and there is a trend towards more orderly and technical government action in this sphere. For example, because basic installations and, in many cases, private capital are lacking, Governments have been obliged to undertake the construction of railways, highways, ports, electric energy plants and irrigation works. Similarly, the need for Governments to expand or establish the various services required for economic development has been caused by the growth of the economy. As a consequence, State expenditure on health, education, research and technological training services, communications and, in general, on the branches of public administration connected with economic life, has multiplied or is tending to expand.

But in Latin America the role of the State in promoting conditions favourable to economic development is not restricted to the above expenditures. Its functions are even more important when considered from the angle of the need to increase national savings and to channel investment towards productive activities. A serious responsibility for the adequate distribution of social expenditure rests upon the public sector. This is because the most suitable investments from the aspect of the over-all economy do not always coincide with the interests or inclinations of the private investor in countries where consumption has absorbed and tends to absorb a growing proportion of income, where an exaggerated propensity for luxury consumption or for non-productive investment exists among social groups with a saving capacity, or where a substantial share of total savings usually emigrates abroad. Fiscal measures are thought to be among the most suitable, if not the best, instruments for accomplishing social aims. They may be used to create incentives for those activities considered as most suitable, to apply higher taxation to activities of the opposite kind, or simply to attract a share of private income to the public sector by means of taxation or loans, in order to invest it in the most appropriate manner. Each one of these methods has been used in the different Latin American countries. All, or practically all, the pertinent legislation includes fiscal incentives and penalties based on economic desirability and the practice of attracting savings for direct or indirect public investment is becoming widespread. A powerful influence in favour of this last practice has been exerted by the need to obtain capital and credit for specific private activities, particularly in agriculture and industry, which it has been thought necessary to encourage and which have no other satisfactory financial resources than those of State credit institutions.

The pressure, in terms of the need for a steady expansion of State functions and expenditure, has not only been exerted by economic requirements. In most cases, the demands of social welfare have, with no lesser intensity, taken an increasing share of public expenditure. Perhaps the outstanding example in practically all the countries is the appearance and expansion of social

security and welfare agencies, which have often required heavy public outlays. Housing problems for workers and certain sections of the middle class—as a result of industrialization, of external and internal migration and of the growth of urban centres—have frequently implied a charge on the State, given the economic and institutional conditions which make this type of investment unattractive to private capital.

A substantial additional burden for the governments of countries which have experienced inflation has been the policy of maintaining relatively low prices for essential commodities and for certain goods and services of prime necessity, such as fuels, transport and some raw materials required for consumer industries. In some cases, the subsidies granted for these purposes have been absorbing increasing portions of the budget, as compared with smaller increments in current expenditure on administration and public investment.

Because of these circumstances, the problem of fiscal expenditure has acquired greater importance in economic policy. The establishment of priorities for the different requirements has become more difficult and demands of an economic nature often appear to compete for a greater share in the budget with those of social welfare, or administrative expenditure with funds devoted to investment. The absence of over-all programmes for economic development in almost all the countries has aggravated the situation. A comparative analysis of public expenditure in the Latin American countries thus appears desirable, as the starting point for more ambitious research on the subject. A knowledge of the way in which fiscal resources have been invested during recent years and an examination, as far as it is possible, of the circumstances which apparently determined their distribution, are both indispensable for any attempt to discover certain criteria of evaluation which might serve as points of reference for public expenditure.

This problem is closely related to the broader one of the structure of taxation in Latin America. The most rapid solution of meeting the growing requirements of the State appears to lie in an expansion of the tax system. There may well be broad possibilities for increasing fiscal revenue in most of the countries. Nevertheless, before giving any opinion on this point, it is essential to study individual tax systems and to consider their effects upon the different sectors of the economy. The aims of fiscal policy in relation to economic development are not in fact confined to raising public investment, but rather have the broad objective of stimulating a more rational use of the aggregate community's resources, with a view to increasing the national product. Therefore, in addition to the possibilities of increasing taxation, the validity of specific obstacles of an economic and political nature, which have to date hindered more definite action by the public sector, must also be examined. A first limitation is the low level of *per capita* income and the impossibility or undesirability of reducing the consumption capacity of broad sectors of the population. As regards the higher-income groups, the major obstacle appears to be the danger that the incidence of very high taxation will discourage private investment or will cause excessive outflows of capital. Political limitations are imposed by the resistance to higher taxes in certain, and often power-

ful sectors, by the absence of tax consciousness on the part of public opinion which facilitates evasion and by the inadequate technical level of the public administration for the efficient handling of fiscal resources and expenditure.

Because public saving (assuming it to be the difference between ordinary revenue and current State expenditure) is insufficient to cover governmental requirements, recourse to the public debt would appear to be the most logical procedure to meet investment requirements. In reality, numerous economic and institutional factors have limited the use and the efficacy of this instrument, both as regards the external and internal debt. In contrast, Governments have frequently used loans of an inflationary nature. Although such loans have not been the only cause of inflation and their use has at times been determined by very compelling factors, it seems clear that the pressure of fiscal expenditure has contributed on a large scale to the inflation in most countries and that this method has often been used as the easiest alternative to the adoption of stricter taxation measures. Inflation in turn has had a negative effect on financial markets, has increasingly hindered the normal use of public credit and at the same time has created new situations which have prejudiced economic development policy by obliging the State to raise expenditure or by reducing its real income. A study of inflation in Latin America is outside the scope of part II, but the role of inflationary methods in financing the public sector cannot be excluded from an analysis of fiscal policy.

Exchange policy presents a similar problem. The economic phenomena related to that policy exceed the limits of fiscal action as such. Nevertheless, in so far as the repercussions of exchange policy on the fiscal system can be appreciated, particularly in those cases where such policy was used to replace methods considered more orthodox by the treasury, reference must be made to them so that a broader view of the framework of public finances can be obtained.

The subsequent examination of fiscal policy in the Latin American countries is a preliminary study of the aspects mentioned in the above paragraphs, especially with regard to their effects upon economic development. This initial effort has met with many serious limitations, particularly because of the poverty of statistical material and the individual classification criteria which hinder comparability between the different countries. Nevertheless, it was felt essential to carry out this first analysis with the deficient technical elements available.

The conclusions or appreciations to be drawn from the analysis will doubtless be very preliminary, but they reveal important aspects of fiscal policy. In particular, they may awaken interest in this subject and lead to new studies and to improvements in statistical methods, enabling subsequent progress of greater significance to be made.¹

¹ The sixth session of the Economic Commission for Latin America recommended to the secretariat that research be continued on the monetary, fiscal and exchange policies necessary for the execution of development programmes (resolution 81 (VI)). In accordance with this recommendation, the secretariat is broadening its studies on these aspects and the results will be available in due course.

Chapter I

PUBLIC EXPENDITURE

I. DISTRIBUTION OF PUBLIC EXPENDITURE BY ADMINISTRATIVE LEVELS

Before analysing the composition and trends of public expenditure in Latin America, the role and relative importance of the various political and administrative levels must be defined, as well as those of the autonomous institutions whose significance as instruments of economic policy throughout the region has increased in recent years.

The way in which public expenditure is distributed among the central government, the states, departments or provinces and the municipalities varies considerably in different countries. (See table 1.) In Brazil, outlays by the central government represent only about 50 per cent of the aggregate, while the relative importance of the states is apparently increasing. In Colombia and Ecuador, the share of departmental governments and municipalities has risen to a third of the total during recent years. At the opposite extreme are Chile and Peru, where central government expenditure accounts for some 95 per cent or more of the consolidated budget.¹ There are other cases—Argentina, Mexico and Venezuela—which provide examples of an intermediate position. Among the countries considered here, Argentina and Brazil alone show any trend towards decentralization. In Chile, Peru and the Central American Republics, expenditure is already concentrated to a very marked degree in the hands of the central authority; in Colombia, Mexico and, to a lesser extent, Ecuador, there has been a visible increase in the percentage corresponding to the central government during the last few years.²

The centralization of public expenditure appears to bear as much relation to the tax structure in each country as to the form of political organization. In Brazil, where the states have substantial sources of revenue—sales taxes, for example, which provide the highest yields within the tax system—any increment in these resources affects their relative position. In Mexico, however, where the principal taxes are assigned to the federal authority, local governments have declined in importance. In Venezuela, where fiscal receipts have been increased mainly by items corresponding to the central government, such as revenue from hydrocarbons and income tax, the share of the states in expenditure—moderate as it is—has been maintained only through transfers from the national treasury.

¹ Despite the absence of statistics, it is thought that the Central American countries are in a position similar to that of Chile. See also *Taxation policy and economic development in Central America*, chapter II (as yet unpublished), by ECLA and the Fiscal Division of the United Nations.

² In Venezuela, under a constitutional ruling, the national treasury is obliged to transfer a fixed portion of budget revenue to the states.

^a Gross expenditure, including transfers between levels.

^b Excluding autonomous institutions.

^c For provincial governments and municipalities, figures based on the budgets.

^d Excluding autonomous institutions and the Dirección General de Pensiones.

The position of the municipalities, whose receipts are mainly derived from taxes on trade and consumption, is quite different. The over-all trend is towards a concentration of greater revenue, and therefore of a greater volume of public expenditure, in the larger cities; those municipalities which have not developed economically depend thus to an increasing degree on meeting their requirements through the budget of the central government or through subsidies.

The distribution of public expenditure by territorial levels also has an important bearing on its nature and composition. Setting aside non-economic considerations, there are public, social and cultural services which are traditionally the responsibility of provincial governments and municipalities. For many reasons that need not be

enumerated here, these services are usually carried out and administered more efficiently at the local level than by the central government. A necessary condition for the competent performance of these functions is that the local authorities be provided with the fiscal resources required for their rational fulfilment, by means of either some type of taxation or transfers of funds from the central authority. Nevertheless, decentralization of expenditure may lead to an exaggerated shift towards current outlays and non-reproductive investment, unless it is accompanied by adequate co-ordination between the different political and administrative agencies.

This type of situation may arise for a number of reasons. One may be greater pressure exerted on local governments by immediate and short-term requirements in the spheres of administration and social welfare, since the management and solution of economic matters—especially those relating to development—are usually considered in the main as a responsibility of the central authorities. Another is that, even in those cases where regional or local authorities pay greater attention to economic development, their field of action is limited by their territorial jurisdiction, the size of their markets and the limited funds available. A third reason, and the most important, is that when public expenditure is more decentralized the decisions as to priorities and objectives are shared by many authorities, each with its own views, which implies less unity of purpose and, possibly, less efficient utilization of government resources.

This does not mean that general agreement always exists within a central government or that satisfactory methods are used for establishing priorities. Nor does it signify that, to establish such priorities, the concentration of public expenditure is a prerequisite. There is no doubt that development and administrative co-ordination programmes are also lacking among central authorities. The point is that these problems become more acute with increased decentralization of expenditure and there is a greater possibility that public resources will be inefficiently utilized from the standpoint of economic development; co-ordination between the central government and regional or local authorities becomes even more important for an adequate investment policy in these cases.

The problem is different for those autonomous institutions or independent organizations which carry out specific activities with treasury allotments and sometimes with other additional resources. This category usually includes agencies of very different kinds, such as: public enterprises of a commercial or industrial nature; institutions for building houses or executing certain types of public works; agencies designed to regulate productive activities or markets for certain products; agricultural or industrial credit establishments; development corporations; and social security institutes. The degree and form of government participation in their resources and administration are also very different. Broadly speaking, this type of organization has arisen and developed first because some functions require operating, financing, administrative and accounting methods which are different from those normally used in public administration; secondly, because government departments may be prohibited from undertaking certain activities or cannot satisfactorily accomplish them. Credit and banking transactions, participation in mixed-capital enterprises, com-

mercial and industrial operations, in general, are some examples.

The study of fiscal policy and its effects upon economic development leads at once to a consideration of those institutions which the State normally entrusts with certain public investment responsibilities, such as agencies with specific tasks (housing, electricity, etc.), official credit banks and, most particularly, development corporations and similar agencies. When these institutions operate exclusively with funds from the national budget, the fact that the investments are channelled through an autonomous agency makes no substantial difference in terms of their effects. In contrast, when these agencies mobilize other types of financial resources, through the attraction of private domestic savings or the receipt of foreign loans, the effects on the economy are more profound than in the case of other types of investment. This is so not only because of the size of their operations over and above official allotments, but also through their effects on the formation of savings, on the channelling of private investments and on the country's international accounts. Any complete study of fiscal policy should include an analysis of the operations, and in particular of the expenditure, of autonomous institutions of this nature. But sufficient data for this purpose were not available and, as a consequence, only those funds contributed by the government sector for the activities of such agencies have been included here.

Another group of autonomous institutions which must figure in any study of fiscal policy consists of those acting as an instrument for the transfer of income. In some cases, these transfers are made through exchange policy or the purchase or sales prices for certain products; they often have direct repercussions upon the income and expenditure of the State or upon its capital account. In other cases, the transfers are made directly, as in the instance of the special agencies for amortizing the public debt and of social security institutions.

These last are of special significance when analysing government operations. Among the accounts included here, social security payments have alone been considered and obligatory private contributions have been excluded. A more complete analysis might cover total receipts and expenditures of this type within the whole public sector, since obligatory private contributions may be compared to taxes. Another major aspect of social security as an instrument of fiscal policy is that of the type of investment made by such institutions. In some countries, their reserves form an important share of the funds available on the market for official securities. In recent years, public investment—as well as part of current expenditure during the last few years—has been financed in Argentina with loans from social security funds. In most cases, social security funds and institutes make direct investments, thus representing a very significant element in capital formation and the composition of investment.

The importance of autonomous institutions has increased considerably in recent years, in regard to both their number and the proportion of the fiscal investments channelled through them.³ It should also be noted that

³ The increased number of these institutions has created problems of public administration, particularly as regards the co-ordination of their activities with those of the central government.

(Continued on following page)

a large share of the credit obtained from international financing bodies has been allocated to these institutions.

II. THE GROWTH OF PUBLIC EXPENDITURE

Public expenditure in all the countries of Latin America rose considerably during the war and it has continued to grow throughout the last ten years. Since 1945, the outlays of central governments have at least doubled and in some cases have multiplied several times at current prices. A comparison based on current values naturally lacks significance, in view of the great variations in the prices of goods and services that have taken place in the different countries. Table 2 shows the real in-

creases in public expenditure as compared with 1947, and the varying degrees of growth within the general trend. Expenditure in Argentina, having risen 35 per cent in 1951, declined thereafter until by 1953 it was 25 per cent above the 1947 figure. The substantial increase in Brazil by 1954 amounted to some 64 per cent above the base year and the increment would have been greater still if both local and central governments had been included. In Colombia, Ecuador, El Salvador, Peru and Venezuela, real expenditure almost doubled; increases in Chile and Mexico were somewhat smaller. Whereas the figures for Guatemala rose by only 30 per cent, there was a sharper upward trend in the other Central American countries—Costa Rica, Honduras and Nicaragua.

Sources: See table 1; for local and central governments in Argentina, the estimates are based on annual budgets.

^a Index represents 1950 = 100.

^b For the fiscal years between 1946/47 and 1953/54 inclusive.

Average *per capita* statistics of public expenditure give a better illustration than aggregate figures of the role played by the Government in the provision of services for the population. State expenditure has risen in all countries at a much rapid rate than demographic growth. This reflects the expansion in the public sector's activities, although in some cases—that of Argentina in par-

ticular—there are fluctuations from one year to another. (See table 3.)

However, there are still important differences in the proportion of the general services provided by individual Governments. While the technical limitations to this type of comparison must be borne in mind, table 4 indicates *per capita* expenditure, in 1950 dollars, and its relationship to *per capita* income. Ecuador, El Salvador, Guatemala, Honduras, Nicaragua and Peru appear with the lowest figures, despite the considerable increase in public expenditure that has taken place in all these countries over the last ten years. Conversely, Costa Rica shows a relatively high percentage, attributable to the

(Continued from previous page)

Some of these problems are of particular interest to fiscal policy, but in view of their nature they are beyond the scope of this study. Nevertheless, much of what has been said in the preceding pages on the need for close co-ordination between the different administrative levels in an economic development policy would also apply here.

broad field of social activities which has for many years been a feature of its government. The high figures for Argentina and Chile undoubtedly correspond to their greater degree of development. Venezuela's position is the result of the substantial revenue accruing to the public sector, which has increased budget expenditure to an exceptional degree and has expanded the services and investment of the State.

With very few exceptions, the relationship between real public expenditure and the real gross product has remained constant or has shown an upward trend over the last ten years. Only in Guatemala are their statistical indications of a decline in the share of the central government. In Argentina and Brazil the tendency is for the public sector to play a more important part; this is also true of Venezuela, although government expenditure in this case has grown less rapidly than the gross product during more recent years. In Mexico and Colombia, the coefficient rose considerably in 1954, despite a drop in the percentage ratio for some individual years.

The size of governmental participation in the gross product and the recent evolution of this share are due to several factors. In Venezuela, the cause lay in the large-scale expansion of petroleum production and the greater share of the State in the revenue from that industry, which has increased the resources of the public sector and, consequently, its expenditure. Among the determinants in Colombia and other coffee-producing countries was the increase in either income tax or export surcharges which followed higher coffee prices. In addition,

some of these countries have had recourse to external and internal loans. Greater public expenditure was possible in Honduras and Costa Rica because the

tax system was reorganized during the last decade and, in particular, because higher taxes were levied on the banana-exporting companies. In Mexico, the growth of Federal expenditure was mainly financed by higher taxa-

tion, distributed over different types of taxes. In Chile, the public sector maintained its share of the gross product not only by an increase in taxes, but also by resorting to bank loans. (See table 5.)

The different components of public expenditure, current outlays, transfer payments and public investment have shown varying rates of growth. Current expenditure includes both administrative expenses and payments for ordinary educational, health, social welfare and defence

services. Its relative importance within total expenditure shows a tendency to decrease. This trend has become particularly apparent since 1950, although there were signs of it at an earlier date in some countries. (See table 6.) Exceptions to this general rule are found in Argen-

Table 6. Latin America: Distribution of public expenditure within the central government (Percentages)

^f 1945/46, 1950/51 and 1953/54.

Chile, Ecuador and Guatemala, where the participation of current expenditure has increased, and in Venezuela, where the coefficient declined between 1950 and 1952 and rose again in 1954.

Transfer payments here include central government contributions to provincial governments and municipalities, payment of interest on the public debt, contributions to social security and similar institutions, retirement and old-age pensions, welfare assistance, and subsidies paid directly by the treasury. The heterogeneous nature of this category is reflected in the diversity of its trends in the various countries. Thus, its relative position within total expenditure, while remaining constant in Brazil and Venezuela, shows a substantial increase in other countries such as Argentina, Chile and Mexico. Conversely, the share of transfer payments declines in Central America because of the stability or reduction in absolute terms of interest payments on the public debt as against an increase in budgeted expenditure.

As a general rule, investments follow an upward trend, except in some of the larger countries. The increases in public expenditure have been predominantly used for capital formation, this tendency being particularly marked in countries such as those of Central America which have only recently embarked upon a policy of economic development. Despite the greater expenditure under the heading of transfer payments, investment in Mexico has continued to rise within the whole. On the other hand, a similar phenomenon in Chile has occasioned a sharp fall in the proportion of the budget devoted to capital formation. The drop in public investment was particularly pronounced in Argentina, from 35 per cent of total expenditure in 1945 to 21 per cent in 1954; whereas there was relative stability in Brazil. The case of Venezuela is different, because between 1945 and 1952 the proportion of public investment within total central government expenditure rose from 28 to 39 per cent, at the expense of current expenditure, while the trend has been reversed in recent years, when the investment coefficient has declined, falling to 33 per cent by 1954.

These aggregate figures scarcely provide more than the broad outlines of the real distribution of public expenditure; in consequence, very few conclusions as to the utilization of State resources for purposes of economic policy can be drawn from them. Expenditure within each of these three broad categories will therefore be analysed in greater detail in the following pages, for those countries where sufficient data are available.

III. THE COMPOSITION OF CURRENT EXPENDITURE

Current expenditure has been divided into four categories for the purposes of this analysis, i.e., general administration, national defence, education and health.

The first group includes all remunerations and purchases of non-personal goods and services for the departments composing the ordinary machinery of government; it comprises the legislature and the different ministries in charge of internal order, foreign affairs and tax administration, as well as salaries and normal expenditure on dependencies of an economic nature (agriculture, trade, industry, etc.). Where it has proved impossible

in the case of these last to distinguish current expenditure from investment, their aggregate outlays have been classified under the heading of investment.⁴ This method implies an overestimate and does not allow any satisfactory comparison of the different categories.

Although expenditure on general administration has increased, just as it has for the other categories, in absolute terms (both in nominal and real values), its share of total current expenditure shows differing trends. In Colombia, El Salvador, Guatemala, Nicaragua and Venezuela, the percentages in 1954 were lower than ten years previously, although in two cases—Guatemala and Venezuela—they have risen since 1950. By contrast, the proportion in Argentina, Brazil, Chile and Costa Rica has tended to increase, the upward movement for Argentina having been particularly marked. (See table 7.) No economic assessment of this type of expenditure can be made simply on the basis of general statistics. The increase may have originated either in expanded and improved public services or in the more equitable remuneration of civil servants and would represent real progress in public administration. But it might also reflect the employment of more personnel and bureaucratic expenditure unaccompanied—for various justified or unjustified reasons—by greater productivity in the governmental sector.

This situation may be more readily understood if the number of public administration employees is compared with the total active population and, in particular, that employed in services. Table 8 follows this procedure, with the addition of a further column to show the results of this comparison when persons employed in agricultural activities are excluded from the active population; this is done to overcome the deficiencies as regards rural man-power in the region's demographic statistics. The United Kingdom has been selected as a reference point outside Latin America because it provides the most complete data on this subject and because its public administration is considered to be one of the most efficient and has one of the highest ratios in relation to the active population. It will be seen that Argentina has the highest ratio for government employment, followed by Guatemala, Bolivia, Venezuela and Chile. Argentina has higher public employment figures than the United Kingdom in all cases, while in the other four countries only statistics relating to the active population excluding agriculture and to services in general are higher. This leads to the assumption that in Latin America—particularly in the five countries concerned—the coefficient of current administrative outlays may be over-estimated, implying that there are other alternatives for a more productive distribution of expenditure in the public sector.

Because of its special nature, defence expenditure is usually classified apart. The inclusion of current expenses such as pay or allowances, rations, purchases of equipment and other similar outlays constitutes no problem. On the other hand, it has been discussed whether military installations should be classified under investment. The prevailing practice is to treat them as current account expenditure, since they make no contribution to a country's productive assets in the sense of providing goods

⁴ This method had to be used in the case of the Central American countries because of the way in which their statistics are presented.

^a Excluding defence, education and health services.

and services that can be added to the volume of national income.⁵ Nevertheless, wherever possible in this study, military installations have been separated and have been classified as a special group within investment.

⁵ See *Budgetary Structure and Classification of Government Accounts* (ST/ECA/8), United Nations publication, Sales No.: 1951.XVI.3, February 1951, pp. 16-17.

Although other reasons exist which may justify defence expenditure, an increase or an excessive share of such outlays in a budget represents, from the strictly economic standpoint, a withdrawal of resources from the formation of reproductive capital or from social and cultural improvements. The relative magnitude of defence budgets in some countries of the Old World has at times

made it almost possible for their economies to grow.⁶ In Latin America, partly because armed forces have increased and partly because modern equipment costs more, not only has defence expenditure risen in absolute terms, but in some countries its relative share in the budget has also expanded. (See again table 7.)

Some circles believe that all expenditure on education and health should be classified under investment, since these services contribute to the formation and improvement of human capital, which is as necessary as physical capital to economic development. In accordance with a somewhat narrower criterion, only investments of a physical nature have been considered as such in this study, although a separate grouping has been established within current expenditure so that investments in education and health can be considered individually.

The sums allocated to education in the different Latin American countries absorb from 8 per cent to over one-third of current expenditure; those devoted to health,

with some exceptions, tend to be somewhat lower, as was seen in table 7. In most cases there have been few variations in the relative share of such expenditure during the last ten years, but there seems to have been a greater increase in the Central American countries, excluding Costa Rica, than elsewhere in the region. It should be recalled, however, that Costa Rica's expenditure on education has been very high for a long time past.

To obtain a proper estimate of the distribution of ordinary expenditure, a comparison should be made of the *per capita* disbursements on each of the principal items. Expenditure on general administration represents the major outlay in all the countries and is followed by that on defence, except in Chile and some Central American Republics where outlays on education rank second. The trend in the distribution of expenditure during the post-war years shows that the heaviest *per capita* increases in almost all the countries occurred in outlays on education and health, but disbursements for general administration expanded more in Argentina and Costa Rica, while the increment in defence expenditure was more rapid in Ecuador and Venezuela. (See table 9.)

IV. THE NATURE AND EVOLUTION OF TRANSFER PAYMENTS

Disbursements of different kinds are grouped under the heading of transfer payments within the budgets of central governments. Their common feature is that they do not constitute an element of final consumption by general administrative services but represent a shift of purchasing power to other sectors of the community.

Some transfer payments can be made among undertakings which form part of the public sector. This happens in the case of subsidies and of budgetary contributions by the central government to provincial governments and municipalities or to decentralized agencies performing public services which are normally a governmental function. Transfer payments of this type are very important in some countries. In Venezuela, for instance, budgetary contributions to the states represent over 90 per cent of all transfer payments. In Costa Rica, sub-

sidies to municipalities have risen during the last ten years and their relative share of aggregate transfer payments has grown from 17 to 55 per cent. Something similar has occurred in El Salvador, where, in relation to 1947, such transfers were 57 per cent higher in 1950 and still 30 per cent greater in 1954.

In Chile, Ecuador and Peru, aid of this type granted to non-profit-making organizations is particularly interesting. Such agencies include teaching, welfare and social assistance institutions, which provide public and cultural services but are organized on an autonomous basis and do not form part of the government machinery. In some cases they are simply private groups, such as universities, colleges, official and private welfare agencies and institutions for the protection of children. The importance of this type of transfer payment has increased over the last ten years, having risen in Chile and Ecuador from 6 to 9 per cent of total transfer payments and in Peru from 35 to 39 per cent. (See table 10.)

^e Fiscal years 1945/46, 1949/50 and 1953/54.

In Argentina, the proportion of transfer payments made to provincial and local governments rose from 24 per cent in 1945 to 35 per cent in 1950 and to 36 per cent in 1953. Transfer payments under this heading in

Argentine pesos amounted to 195 millions in 1945, to 1,356 millions in 1950 and to 2,577 millions in 1953. The principal reason for the increase lies in the reform of the fiscal system at the end of the 'forties; the central

government assumed responsibility for the administration of several taxes which had formerly been handled by the provinces and municipalities, and the corresponding payments were later transferred to these levels. Transfer payments in the form of subsidies to non-profit agencies are also important in Argentina and are classified in table 10 as "grants-in-aid". The recipients were mainly universities or educational and welfare institutions, but this category also includes other autonomous agencies responsible for marketing products such as meat, cereals and yerba mate. Some of these subsidies originated as direct allotments from expenditure in the national budget, but the largest share in recent years has come from the legal participation of these agencies in the revenue from certain taxes.

Brazil also demonstrates a considerable increase in the contributions of the Federal Government to states and municipalities, as well as in the grants-in-aid to non-profit-making institutions which perform public services. In 1954, these two items represented 37 per cent of all central government transfer payments.

The grouping of these disbursements under the general heading of transfer payments is justified because, given the autonomy in expenditure enjoyed by such institutions, no prior assessment can be made either of the shares to be used for consumption and for investment respectively, or of the composition of such expenditure. Any consolidation of the public sector's accounts would have to make this distinction, and the various items would have to be grouped according to the final destination of the expenditure.

Even more important, from the economic viewpoint, are those operations which really imply a transfer of revenue from the public to the private sector, such as payments of interest on the public debt, pensions, social security contributions and subsidies to specific productive activities.

The predominant trend in most countries during the last ten years has been towards a relative reduction in the interest paid on the debt in the central government budget.⁷ Moreover, in several cases—Argentina, Brazil, Chile and Costa Rica, for example—a decline is apparent in the *per capita* expenditure earmarked for this service. In Mexico and Peru there has been a fairly large *per capita* increase. With regard to Venezuela, amortization paid during the fiscal year contributed to the high figure for 1953-54.

The more interesting aspects of the debt will be examined elsewhere;⁸ but it is pertinent to note here that the financial burden originating in the government debt represents a relatively unimportant factor in the budgets of the Latin American countries mentioned above. There are two main reasons. Firstly, governments have recently made little use of the traditional sources of public credit, frequently resorting to other, and less orthodox, means of financing the deficit (principally Central Bank issues), largely because domestic financial markets have been

weakened by inflation. Secondly, a substantial part of the newly-contracted debt has been channelled through the autonomous agencies responsible for paying the interest. Hence the over-all financial incidence of the public debt is far greater than that revealed by central government statistics.

State expenditure on welfare and social security has shown increases of some significance in almost all the countries listed in table 11. Nevertheless, two further important aspects should be considered. First, with the exception of Chile and, to a lesser degree, Argentina, the sums spent by Governments, in terms of *per capita* contribution, are small in relation to other items in the budgets. (See again table 8.) This is probably because social security is a relatively new institution in many of the Latin American countries and, in many cases, because its sphere of activity does not yet extend to all economic sectors or to all geographic areas. Secondly, there are other types of transfer payments that have grown more rapidly than welfare outlays, with the result in some countries that there has been no appreciable increase in the participation of welfare in aggregate current expenditure.

Particularly notable in some countries is the substantial increase which has taken place in expenditure on subsidies for public utility enterprises and private economic activities. This type of transfer payment has been of special importance in Argentina and in other countries which have experienced a period of prolonged inflation, such as Brazil, Chile and possibly Mexico. The main objective has been the maintenance of low prices and tariffs for essential consumer goods or services of public interest, losses by individuals and corporate bodies being offset by direct state subsidies. In other cases, subsidies have been granted to cover the deficits of state undertakings which, although they operate at a loss, are considered to be of national importance. Assistance of this latter kind has also been employed in other countries.

In Chile, direct subsidies to public utility companies and to the private sector—particularly transport—were of little significance in 1945, but they absorbed some 16 per cent of all transfer payments in 1954 and represented a substantial *per capita* outlay. In Mexico, the item of subsidies and grants-in-aid is the largest within the category of transfer payments and has also shown the greatest *per capita* increase over the last ten years.

Subsidies granted through the budget in Argentina absorbed 9 per cent of transfer payments in 1950 (340 million pesos at current prices), declining to 5 per cent (389 millions in 1953). The year of maximum expenditure on this item was 1951, when it amounted to 964 millions. The main beneficiaries have been the meat packing plants, railways, airline companies and the Instituto Argentino de Promoción del Intercambio (IAPI). Nevertheless, the picture would still be incomplete without a mention of two very important events. Railway operation has in recent years shown a heavy deficit which has not been covered by the Government except in 1947. It may be assumed that the losses were not offset during the rest of the period or that compensation was made through other channels. Most of the subsidies to private activities were not provided directly by the central government budget, but were paid through IAPI, which, in turn, was financed with profits accruing

⁷ In almost all the countries shown in tables 10 and 11, the figures refer to interest payments, since amortization is included among financial investments. Exceptions to the rule are Peru and Venezuela, where it was not possible to separate interest from amortization.

⁸ See chapter III, part II.

from foreign trade operations and with loans from the Central Bank. This situation has contributed to inflation and to the critical position of Argentina's balance of payments. The subject will be studied in greater detail when foreign exchange policy is examined elsewhere.⁹

In Brazil, subsidies have also increased in absolute terms, although their relative share has declined. Nevertheless, both in this country and in Chile, heavy subsidies have been granted during recent years which were channelled indirectly through the exchange system. The study and analysis of these transfer payments and of their effects upon the domestic economy and on development will be found in the chapter dealing with exchange policy.

V. PUBLIC INVESTMENT

The main contribution of the public sector to the promotion of economic development is made through the budget items devoted to investment. In so far as these investments represent a net increment in the productive capital of a country, they cause direct growth of the national product. They can also exert an influence by providing the economy with basic services and installations, which, in addition to their own contribution to the expansion of production and revenue, also provide

an incentive to private investment. Similarly, the creation of more satisfactory educational, health and housing conditions not only helps to improve the material situation and the productivity of the human factor, but also prepares the physical and spiritual requisites for a more active and better-trained participation of the population in the future economy and for the increasing application of technological progress to productive activities. But, as in the case of the private sector, public investments may be made which do not contribute to the growth of the economy. At the government level, public funds are sometimes spent on installations whose justification is doubtful or on luxury facilities which, while they may be desirable for other reasons, add little or nothing to capital formation. Hence, in order to assess the share of the government sector in economic development, it does not suffice to refer briefly to aggregate figures for public investment; they must be broken down according to their nature and final purpose.

Primarily, a distinction should be drawn between real investment and financial investment. The former represents the purchase of entirely new assets, which are added to those already in existence. Financial investment consists of the acquisition of previously produced assets and, while it may signify investment from the aspect of the public sector, it adds nothing to a country's stock of

⁹ See chapter IV, part II.

capital. This is true, for instance, of public debt amortization, of the purchase of already existing private securities, of the acquisition of buildings, or of payments to private individuals for their shares in nationalized enterprises. Financial investment has, wherever possible, been set apart in this study, since the primary objective is to assess the government contribution to capital formation. Nevertheless, in most cases it has not been possible to separate financial investments from real investments. An illustration might be the purchase of buildings to be demolished or utilized for the construction of public works, when this information is not specified in official accounts.

A second distinction has been made between direct and indirect investment. The former relates to works carried out by the public sector itself, while indirect investment embraces loans granted to private interests for purposes of real asset formation.

Direct investment, which constitutes a high percentage of the total in the Latin American countries, may be carried out by the Government itself or by specialized autonomous institutions. Wherever the nature of the work done by these institutions could be determined, the corresponding budget allotments have been classified under the item relating to the activity undertaken, for example, agriculture, transport, etc. Where this was impossible, public contributions to these agencies have been grouped in one column. These specialized institutions sometimes have extra-budgetary resources at their disposal, such as revenue of their own or internal or external loans, which form part of the public sector's resources devoted to capital formation. Even so, in order to maintain the homogeneity of the figures, the standard procedure has been to include in government investment accounts only those budget allotments set aside for these institutions.

Indirect investment is usually made through special agencies, such as agricultural, industrial, mining and housing credit banks. In a few cases, Governments have granted funds to institutions which make no direct contribution to production, as, for instance, certain mortgage credit institutions, but this is the exception rather than the rule. Budgetary funds for credit institutions have been included in the statistics as government investment, any other resources which these establishments may have used having been disregarded.

The method adopted has, however, caused certain problems. Development corporations in some countries are both credit institutions and agencies carrying out specific tasks and it has rarely been possible to separate the share corresponding to each activity. To overcome this difficulty, the entire government contribution to these institutions has been considered as direct investment,¹⁰ except in those cases where it could be verified that credit activities represented most of their operations, as is true of the Banco Nacional do Desenvolvimento Econômico in Brazil.

There has been an outstanding increase in public investment during the last ten years in Latin America.

¹⁰ For instance, in Guatemala to the Instituto de Fomento de la Producción, in Honduras to the Banco Nacional de Fomento, in Mexico to the Nacional Financiera, and in Venezuela to the Corporación Venezolana de Fomento.

(See table 12.) With the single exception of Chile, all the countries selected show an expansion of fiscal capital formation. *Per capita* investment provides even clearer evidence of the degree of growth and its relationship to other budgetary items. In Brazil, the *per capita* increment amounted to 81 per cent between 1947 and 1954, in Colombia to 15 per cent, in Ecuador to 8, in Mexico to 29, in Peru to 233 and in Venezuela to 82 per cent. The most spectacular increases, in general terms, appear in Central America, because in the main it is only since the Second World War that the countries in this area have embarked on a development policy with active government participation. Even in Costa Rica—where the main objective of fiscal policy in 1948-52 was to place the treasury on a sound basis after the civil war—investment has increased considerably since 1953.¹¹ In Argentina, where in 1947 central government investments had declined in relation to 1945, the increase was only 6 per cent from 1947 to 1953.¹² Chile is the one country where government investment has decreased in recent years, the cause being the inflationary spiral during this period. This situation has, in the fiscal field, been manifest in the disproportionate increase of ordinary expenditure and of transfer payments, as well as in the inability of the tax system to provide a volume of revenue sufficient to meet additional outlays.

Nevertheless, the expansion of investment has not implied that its relative position within the whole budget has risen in the same proportion, as current account expenditure and transfer payments have also shown heavy increases, even in those countries where Governments have made considerable efforts towards capital formation. It might thus be enquired whether no possibility exists of even more active participation of the public sector in capital formation, through judicious economies in other types of expenditure.

Most government investments in Latin America are made directly.¹³ The credit activities of autonomous institutions, although significant in some countries, represent only a minor share of government activity. This is partly because at the present stage of development, notwithstanding the great differences of degree, greater attention has had to be paid to basic installations. As may be seen below, investment in transport accounts for the largest share of public investment in almost all the countries.

In order to appraise the nature of investments in relation to economic development, they have been classified in three broad categories. The first, entitled "Investment in productive activities", embraces all investments which contribute directly to productive capital formation, such as agricultural development, transport, energy and funds for the autonomous development agencies. The

¹¹ The statistics for Central America are exaggerated, since they include current account outlays by the Ministries of Economy, Public Works, Agriculture, Education and Health. It was not possible in these countries to distinguish administration expenditure from investment and the budgets of these ministries thus had to be grouped under the latter head.

¹² It should be recalled that official welfare foundations and, to a lesser degree, social security institutions have made substantial investments during this period and such investments are not included in central government statistics.

¹³ As noted earlier, some investments in development corporations—classified as direct investment in table 12—are used for loans to the private sector.

second, which has been called "Investment of a social nature", covers those public works which tend to aid the human factor by improving educational, health and housing conditions. The third category, entitled "others", includes investments which have a less direct bearing on the development of the economy, such as military installations, urbanization and buildings of a different type from those included in the other categories. Apart from the arbitrary element inherent in the classification itself, the available data are not absolutely precise; comparisons between countries are therefore of doubtful value. Even so, some interesting conclusions can be drawn from an analysis of table 13.

In Argentina, investment in productive activities, which in 1947 constituted only a third of aggregate direct investment, raised its share to 57 per cent in 1953. The most significant increases under this heading are found in funds devoted to transport, road, rail, ports, port services and airports. Larger contributions have also

been made to agriculture and energy. Social investment continued to absorb a virtually constant share of the total, with a higher percentage for health services. However, schools, colleges, hospitals, clinics, etc., could not be distinguished from buildings of other kinds and are consequently included under buildings in general. Funds for housing show a low coefficient, but it should be recalled that from 1950 to 1952 budgetary funds for this purpose were much higher than in 1953, and that, in addition, a great deal of housing is included under the item of buildings or has been erected by other types of institution (foundations and social security institutions). During the whole period, buildings and military installations together, despite a decline in the latter during 1953, absorbed a high percentage of direct investment.

Capital formation by the Federal Government in Brazil has been directed mainly towards productive activities, particularly transport. Agricultural investment could not be separated from the total. As for allotments to autono-

^b Fiscal years.

mous institutions, these were assigned principally to undertakings of an industrial nature: Petróleos Brasileiros, the Volta Redonda steel mill, the Fabrica Nacional de Motores, the Companhia Nacional de Alcalis, the Hidroelectrica São Francisco and the Companhia Vale do Rio Doce. Social investment appears with a very low share of the total. Here again, it has been impossible to separate educational and health installations from building in general, which has a relatively high coefficient. It should be noted that in Brazil the states also devote a large share of their expenditure to purposes of capital formation, within which public works of a social nature occupy an important place. In 1954, some 22 per cent of State expenditure and 21 per cent of municipal outlays represented real investment.

For Chile, the figures in table 13 do not include total direct investment because the proportions financed through bond issues (13.8 per cent in 1947 and 7.0 per cent in 1954) are unclassified in the official accounts. As for those which are classified, it may be seen that investment in productive activities has risen considerably, increasing from 56 per cent in 1947 to 66 per cent in 1953. Although there has been an increment in the share of transport, the growth of productive investment is almost entirely due to contributions made to autonomous institutions, particularly to the Corporación de Fomento, which has, during the years under review, carried out large-scale projects in electricity and steel making. Despite the proportional increase in public health installations, there has been no major increment in investments of a social nature because of the relative low expenditure on housing.¹⁴ Perhaps the figures relating to other building include social investment items and

have thus led to an over-estimate. In any event, investment of a military and non-economic type has dropped in relative terms from 36 to 23 per cent over the last ten years.

In Colombia, there has been a decline in the proportion of the total represented by investment in productive activities, which had formerly constituted a high percentage. On the other hand, the share of expenditure on building has increased, although this item includes some investments of a social nature. Official capital outlays on transport continue to be the largest item, although there has been an increase in expenditure on agriculture in recent years.

In Mexico, where the figures in table 13 cover the entire public sector, very high percentages have been invested in productive activities. Furthermore, they rose steadily between 1945 and 1951, reaching 81 per cent of the total in the latter year. While outlays on transport have declined somewhat, those on agriculture and energy have increased.¹⁵ Social investment shows an upward trend, caused mainly by the construction of educational buildings and houses, while there has been a decline in public health items. Figures for military installations are particularly low in Mexico, and these investments, as well as those for other buildings and urbanization, fell from 7.3 to 4.0 per cent between 1945 and 1951.

¹⁴ It should be noted that the building of dwellings has constituted a very large item of investment by the autonomous social security institutions. As against 4.8 billion pesos, at 1950 prices, in funds allocated by the central government to the Instituto de la Vivienda during the period 1945-53, social security institutions made direct investments in this activity of about 8 billion pesos.

¹⁵ Energy here includes electricity and petroleum.

In Peru, the figures reveal an evolution similar to Colombia's, with a relative decrease in productive investment and an increment for buildings. Nevertheless, the percentages for agriculture and transport within the total represent fairly substantial increases.

Venezuelan investment in productive activities rose from 47 per cent in 1947-48 to 67 per cent in 1953-54, mainly because of the rapid growth of expenditure on transport services. Investment in agriculture retained its share, while contributions to autonomous institutions declined. On the other hand, there was a sharp drop in social investment, which fell from 49 to 21 per cent. This reduction affects educational as much as public health installations. With regard to housing, public accounts in 1954 do not record any allotments for the institute in charge of this type of work, which was mainly financed with credits from building enterprises. Investment in building improved its share of the total during the period, while that for military installations rose from 2 to 7 per cent. This means that non-social and non-economic investments represented a proportion of 3 per cent in 1947-48 and 10 per cent in 1953-54.

As a rule, the marked trend in public expenditure in Latin America has been towards raising investment in activities directly designed to foster production. Transport continues to be the main object of this type of government activity, although the importance of energy has also increased in many countries, particularly through the action of specialized official institutions. To a lesser degree, agricultural investment has followed a somewhat similar course. Outlays of a social nature continue to absorb a considerable share of public investment, although their relative importance has tended to decline in some cases. As for expenditure less closely related to economic development, its relative share has decreased, with the exception of the one or two countries specifically mentioned above.

VI. PUBLIC EXPENDITURE IN RELATION TO THE WHOLE NATIONAL ECONOMY

The analysis of the effects of public expenditure upon the economy as a whole is a complex subject, which would require consideration of many elements not included in this study. Nevertheless, on the basis of the data contained in preceding pages, some remarks can be made which may help to clarify the functions of fiscal policy in relation to development problems.

Public expenditure not only represents a very substantial share of national income in quantitative terms, but, because of some of its intrinsic features, it also plays a unique role with respect to income variations. The relationship existing between government expenditure and national income in some Latin American countries is shown in table 4. The coefficient appears to be smaller—between 10 and 15 per cent—in Ecuador, Mexico, Peru and the Central American countries. The highest figures are registered in Argentina with 23 per cent, Venezuela with 21, Brazil with 19, Colombia with 18 and Chile with 17 per cent.

Apart from the relative importance of these amounts within aggregate national income and domestic demand, public expenditure has greater autonomy, since it depends principally on the independent decisions adopted

at the national level. In fact, in countries such as those of Latin America, where the export sector is very largely responsible for the fluctuations of production and income, the decisions of the export sector in their turn depend on world market conditions. Because of their importance within aggregate income, exports thus tend to become the dynamic element in economic life, but the variations affecting their volume and price originate abroad. Production for the domestic market is planned on the basis of estimates of future national demand, which are strongly influenced by the prospects for those export activities whose specific importance within aggregate income is greatest. In addition, the internal effects of investment in production for domestic purposes are weakened by the fact that much of such investment consists of expenditure abroad, in the form of imports of capital goods and raw materials. Bearing in mind the existing differences in the evolution of the Latin American countries, investment in productive activities for domestic consumption in less highly developed countries has, broadly speaking, not attained the autonomous nature and dynamic role which characterize private investment in highly industrialized economies. On the other hand, public expenditure has no reason to be subject to foreign market conditions or to fluctuations in domestic demand; in this sense it enjoys autonomy because, within rational limits, economic authorities are at liberty to establish the volume of expenditure and, as a result, the funds devoted by the public sector to the community's effective demand. It is true that a decline in production and income in other sectors can bring about a reduction in public revenue which obliges the Government to reduce its outlays, and this has frequently occurred in Latin America especially in countries which depend largely upon their foreign trade. In this case, the attitude of the authorities would reflect what was taking place in the rest of the economy. But such a situation is not inevitable, and, in fact, the public sector, by means of higher taxes or any of the known forms of indebtedness, is well able to maintain and even increase its expenditure when its current revenue is reduced. The policy of deficit spending consists essentially in this type of procedure and has more than once been employed in the Latin American countries.

To this autonomy of the public sector is added the circumstance that in this sector decisions are usually centralized in one or a few responsible agencies, whereas in private enterprise variations in expenditure and investment are the result of an infinite number of uncoordinated individual decisions. Hence public expenditure constitutes a dynamic element in the formation and magnitude of national income, on whose variations it can exert a decisive influence, just as it can neutralize—at least partially—the effects of fluctuations occurring in other sectors.

Modern fiscal policy, which is based on this fact, is thus a powerful instrument which requires extremely delicate handling. The nature and size of public expenditure can be utilized in a positive way—and in fact has been so used in Latin America—to offset inflationary pressure arising from international trade or, more frequently, to maintain adequate levels of employment and income when exports decline. In this way it helps to preserve a balanced position which is favourable to economic development. But an opposite effect is also possible. A con-

traction in public expenditure in times of recession has on more than one occasion sharpened the fall in income and provoked an unnecessary interruption in the process of growth. More frequent still have been instances where an exaggerated increase in public expenditure has occurred at times when the levels of income and the supply of goods and services made it inadvisable to expand purchasing power. In such cases the public sector has absorbed a higher share of aggregate available goods and services than it has been able to finance from ordinary fiscal income or from transfers of savings from the private to the public sector (measured by the proportion of the public debt in private hands). Inflationary pressure thus arises, which, if sustained, would seriously prejudice economic development.¹⁶

Development is as much influenced by the composition of public expenditure as by the general level of such outlays and their relationship to the other groups contributing to national income. The governmental sector distributes its resources between consumption and saving, in the same way as private individuals, and both categories of expenditure provide innumerable possibilities for the use of resources, which have different effects upon economic life.

Consumption expenditure by the public sector has been analysed in the foregoing sections for several countries of the region under the headings of both current account expenditure and transfer payments. It is unnecessary to repeat what has been said on the role which the different categories of outlay have played within the aggregate. An evaluation of the marginal utility of governmental services depends on the importance assigned to the various needs of the community. Even so, from the economic standpoint, certain criteria can be established as to the composition of public expenditure. From the economic point of view, it is clear that a broad field of action exists in some Latin American countries for a more rational distribution of current government expenditure.

Special reference should be made to the situation in some countries affected by inflation where particular significance has been acquired by those transfer payments or subsidies which maintain specific goods and services of an essential nature at prices lower than those prevailing on the market. The effect upon the redistribution of income, which was apparently the aim of this procedure, is open to discussion, but it is intimately linked with the tax structure of each country. With a progressive tax system, such transfer payments may cause a real improvement for lower-income groups. But in some Latin American countries which have suffered from prolonged inflation, the regressive nature of the tax system has tended to become more pronounced in recent years. As a result, it is highly doubtful whether these transfer payments have contributed towards a redistribution of income and it is very probable that the incidence of the subsidies is actually borne by those who receive them. When the need for greater financial resources to meet this growing item of expenditure has been met by persistent recourse to inflationary measures, and not by tax revenue, the burden is created by higher prices for

the other non-subsidized products, which must also be borne by the consumer.

In addition to these aspects, transfer payments have had other unfavourable effects upon economic development. They have acted in certain countries as palliative measures which have retarded the adoption of sounder methods for attacking the causes of an unsuitable price structure. In some cases, they have artificially maintained very low prices for certain imports, discouraging domestic production and leading to exaggerated consumption which has affected the balance of payments. Everywhere they have been absorbing a continuously increasing share of public expenditure and have thus reduced government resources for capital formation. These statements do not imply that under certain conditions some type of subsidy may not be necessary, as a temporary measure to deal with a transient imbalance or to offset the effects of problems which could not be fully solved except at the cost of greater sacrifices. But the conversion of such measures into a permanent system may lead to undesirable consequences for the economy as a whole and for development in particular.

It seems to be an accepted principle today that one of the major public contributions to economic growth consists in attempting to increase the community's marginal rate of saving; in other words, one of the chief aims of fiscal policy in under-developed countries should be to channel a growing share of income increments towards capital formation. To achieve this objective, the State can use the tax system and budget expenditure as a means both of encouraging private savings and of enlarging its own contribution to investment. On this basis, it may be useful to examine briefly how the public sector has increased investment in the Latin American countries.

The contribution of the public sector to aggregate capital formation varies from one country to another. (See table 14.) In some cases, such as that of Mexico, public investment has contributed over 40 per cent of aggregate capital formation in recent years.¹⁷ The figures for Argentina, Chile and Venezuela, although somewhat smaller, are also high. Except for certain isolated years, the share of the government sector in all countries has never fallen below 10 per cent. Its assistance has mainly taken the form of real direct investment, although by extending credit, the public sector has also contributed to the capital formation of private enterprises.

A comparison of the changes which have taken place in public investment and private investment during recent years is of particular interest. Figure I shows the behaviour of capital formation at constant prices for the public and private sectors, and aggregate investment. During 1945-47, the sharp upswing of capital formation in Argentina was entirely due to the private sector, as public investment declined during that period; the reverse occurred in the following year, but, if a slight rise in 1951 is excluded, since 1949 both public and private investment have followed a downward trend. The outstanding feature in Brazil was the neutralizing effect of public investment, which rose when private capital formation tended to decline and vice versa, within a general trend towards a higher aggregate level of investment. The decisive role of public investment should be noted

¹⁶ See chapter III of part II, and the *Economic Survey of Latin America, 1954* (E/CN.12/362/Rev.1), United Nations publication, Sales No.: 1955.II.G.1, chapter I, Part I.

¹⁷ The figures include the entire public sector in Mexico.

^a The entire public sector.^b The fiscal years were averaged to compare them with data for civil years.

in the case of Colombia. During the last eight years, the real volume of private investment has remained almost constant, with the exception of a sharp fall in 1949; conversely, public capital formation has moved steadily upwards, practically without interruption, providing the sole basis for the aggregate increase in national investment. In Chile, the two sectors have been almost equally responsible for the stationary level of capital formation between 1945 and 1954. Public investment in Mexico has been the major determinant of the rising trend—not very pronounced, but steady—in total capital formation during the last ten years. A similar pattern is evident in Venezuela, where private investment has varied sharply from one year to another, apparently through the influence of the investments made by the petroleum companies, while public capital formation has moved steadily upwards, particularly between 1945 and 1949; since 1952, however, the private sector has made the chief contribution since 1952 to the increase in aggregate capital formation. (See Figure I.)

The influence of official investments upon the gross product is related to the type of investment made. When they are mainly devoted to productive activities, a quantitative increment in available goods may be expected over a fairly short period, according to whether the product-capital ratio in each case is high or low. In contrast, social investment has only an indirect influence upon an increase in the product, or has a very low productivity per unit of capital as is true of investment in education, public health and housing. This factor partly explains the different results obtained in selected coun-

tries from public investment. In Mexico, for instance, in addition to favourable weather conditions, investments in agriculture have contributed to the substantial increase in rural production during recent years. In Argentina, on the contrary, where investments for non-productive activities have been the largest, the rate of growth of the gross product has been much slower, and in some sectors—particularly agriculture and livestock—there has been a recession in relation to previous years.¹⁸ While no claim is made that official investment is the only factor to be considered in both cases, its influence has without doubt been significant in the recent economic growth of these two countries.

Apart from direct investment and the provision of credit to the private sector, a Government can encourage capital formation through its demand for goods and services. The more it spends money within the country—that is, the lower its propensity to import—the stronger will be the incentives to produce the goods required. The variety of government purchases is very great, but, in view of their size, they can help to create an effective demand that is sufficient to induce private capital to invest in new activities or to expand existing installations. This fact acquires a certain practical significance because private sectors in some countries have criticized—not without reason—the excessive official propensity to import, or the official choice of foreign suppliers based

¹⁸ See "The situation in Argentina and the new economic policy", *Economic Bulletin for Latin America*, Vol. I, No. 1, *op. cit.*, p. 26 *et seq.*

on very small differences in price, without due regard to the indirect effects of government purchases upon capital formation.

Competition between the Government and the private entrepreneur, with its effects upon the latter's investment decisions, is another important aspect of the influence of public expenditure upon the whole economy. Government competition may make itself felt in two ways: (a) through the acquisition of productive resources, particularly man-power and technicians; and (b) through the sale on the market of goods and services which are produced by the private sector. The latter proceeding appears to have little importance in general terms. Official investment in Latin America has been mainly directed towards the establishment of basic installations: means of transport, irrigation works, etc. Although in electric power and petroleum industries, there is—at least in some countries—a pronounced trend towards public ownership of the enterprise, individual cases would have to be studied before any opinion could be given, because their character as the public services or basic industries is related to very special circumstances which are usually advanced as the reasons for State intervention. The competition for unskilled labour apparently represents no problem in most of the Latin American countries, be-

cause a high level of under-employment exists in primary activities. This is not so, however, for skilled workers and technicians. The solutions (immigration of qualified personnel, encouragement of technical education, etc.) which have been adopted in areas where competition has become acute, constitute an additional effort of great importance for future development of the region's economies.

As a rule, then, competition by the public sector does not appear to be any great obstacle to private investment. Nevertheless, in some countries and in some very important branches of production, State action is predominant. Undoubtedly, government investment in these specific activities has, sometimes deliberately, discouraged private investment. In the particular case of sectors where foreign capital is concerned, the effect of government intervention may be more important still, because of a broader interpretation of the position of the State in relation to private capital or foreign investment. The reasons for the maintenance of such a policy by some Governments lie outside the strictly economic sphere, and thus any attempt to appraise them would have to take into account, not only the economic aspects, but also political considerations which are beyond the scope of this study.

Chapter II

FISCAL INCOME

I. THE TAX STRUCTURE OF LATIN AMERICA

1. THE OVER-ALL TAX BURDEN

The proportion of tax revenues to gross national income is appreciably smaller in Latin America than in the United States and in the more highly-developed countries of Europe, covering the same general range as in the less developed countries of Europe and Asia. (See table 15.) In Latin America, central government receipts represent from 6 to 15 per cent of the national gross product, except in Venezuela, where they amount to 18 per cent, although, if the taxes paid by the petroleum companies are excluded, the proportion drops to 7 per cent. In the United States public revenue has accounted for approximately 15 to 20 per cent of the gross national product in recent years, while in the more highly-developed countries of Europe for about 15 to 30 per cent. On the other hand, in Burma, Ceylon, India, Spain and Turkey its share varies from 7 to 17 per cent.

The ratio of total public sector tax receipts to gross national product is somewhat similar. In Latin America, this ratio fluctuates from 10 to 22 per cent; in the United States, it ranges from 20 to 26 per cent, and in the highly-developed countries of Europe from about 25 to 45 per cent.

The differences in the over-all tax burden from one country to another are attributable to a variety of causes, such as the level of military and defence expenditure, economic and social programmes financed with government funds, and government social policy. But the main reason for the discrepancy between the incidence of taxation in Latin America, on the one hand, and in the United States and most of the countries of Western Europe, on the other, lies in the relative degree of economic development. An inferior level of development implies a lower tax base. Although the regressive nature of the tax system affects the under-privileged sectors, the fiscal product is much smaller than in more highly-developed countries. Moreover, in many Latin American countries it is practically impossible to tax a substantial portion of the population who are to a large extent outside the money economy. Income taxes, which in the industrialized countries yield high or substantial percentages of total revenue, are much harder to apply. The proportion of potential income-taxpayers is much smaller and the costs of administration relatively greater; in addition, the problem of avoiding interference with stimuli to the investment required for development is in every way more complicated and serious. Systematic accounting is less widely practised and, mainly because of the lower over-all level of economic development, the administration of the tax laws leaves much to be desired.

This situation should not be interpreted to mean that possibilities for increasing tax receipts are exhausted in

Latin America. This is far from being the case, despite the limitations and difficulties imposed by the level of economic development. In the course of this study, some of the ways in which the tax structure can be improved and revenues increased without prejudicing economic growth will become apparent.

Although tax burdens in Latin America as a whole are lighter than in the more highly-developed countries of the world, this should not obscure the fact that there are very significant differences among the Latin American countries themselves. The available data are not sufficiently complete to warrant categorical generalizations. They do, however, seem to justify the tentative conclusion that in general the larger, more developed and more diversified countries of Latin America bear significantly greater tax burdens than the others. This holds true for Argentina, Brazil and—even excluding receipts from copper—Chile. On the other hand, the incidence of taxation in the comparatively small and less diversified economies of Central America and Ecuador is distinctly lower. Mexico is a notable exception to this rule; considering its size and economic structure, the tax burden is relatively light. In Venezuela, the ratio of over-all tax receipts to the gross national product is relatively high, but this is due to the substantial receipts from the large petroleum companies; when such revenue is excluded, Venezuela falls into the group of Latin American countries with relatively modest tax burdens.

Among the general economic factors which have a major effect upon the tax revenue and structure of Latin America, and, consequently, on tax burdens, the chronic inflation to which a number of countries have been subject for many years is worth specific mention. Inflation tends to reduce both incidence and revenues in real terms in the case of certain types of taxes, not only absolutely but also in relation to other taxes. It is apt to create a lag in income taxes which reduces their real burden and yield; tax obligations arising in one year are paid in the next in a depreciated currency. Similarly, inflation greatly alters, as a rule, the incidence of the various taxes. Many indirect taxes, which are comparatively easy to collect and to adjust to inflation, tend to gain in importance. Income tax exemption levels are often forced downward in real terms; the impact of the tax rate undergoes considerable modification; many groups in intermediate-income brackets are forced into the upper categories with their higher rates; and those in the maximum bracket, where the rate ceases to augment, often pay lower real taxes because of currency depreciation. Numerous differential taxes, designed, for example, to encourage industry or discourage the ownership of unused land, lose some of their efficacy. Inflation frequently exalts the problem of taxation of capital gains, particularly from investments which are not especially desirable from the social angle, into one of prime importance; these gains are often so great and so constant,

Sources and notes: Official statistics for the Latin American countries were regrouped by ECLA in the interests of uniformity. In the case of Venezuela and Honduras data for fiscal years were averaged to obtain calendar year figures. Data for European countries were obtained from the *Economic Survey of Europe for 1949*, prepared by the United Nations Economic Commission for Europe. Coefficients for these countries were calculated on national income at factor cost. United States; *Economic Report of the President, January 1956*. The figures for some Asian countries were obtained from The United Nations *Statistical Yearbook 1954*, for central government income, and from *Statistics of National Income and Expenditure*, United Nations publication, series H. No. 8 for the gross national product.

as well as being mainly dependent upon inflation, that they lose their character of fortuitous earnings and become in effect a form of unearned income. Finally, inflation creates a lag of receipts behind expenditure which is liable to reinforce the initial inflationary process and to cause far-reaching effects on the economy as a whole.

2. IMPORTANCE OF TAX REVENUES FROM THE EXTERNAL SECTOR

One of the main characteristics of taxation systems in the Latin American countries is the high proportion of tax revenue obtained from activities directly connected with foreign trade. Table 16 shows the respective percentages contributed by import and export duties, royal-

ties and other taxes on production for export to the total revenue levied by the central government in each of the countries under consideration.¹

In seven of the thirteen countries covered in the table—Venezuela, the five countries of Central America and Chile—the proportion of aggregate revenue accounted for by the external sector was more than 45 per cent, rising to its highest in Venezuela, where it was 75 per cent. In three countries—Ecuador, Mexico and Colombia—the corresponding figure was between 25 and 40 per cent. Only in two countries—Argentina and Brazil—was the external sector of less importance in

¹ For Brazil, Chile and Colombia, the statistics in table 16 represent the total for the public sector.

^a Total public sector.

relation to total revenue, with coefficients of 6 and 11 per cent respectively.²

The specific sources of the external sector revenues vary considerably among the different countries. Income taxes, royalties, payments for exploitation rights, exchange profits, etc., derived from large foreign companies engaged in the production and exportation of a single basic commodity provide a very large proportion of total revenue in two countries, and significant percentages in several others. Of Venezuela's total current revenue, about 60 per cent was derived from the petroleum industry; of Chile's, over 32 per cent came from copper mining and, to a small extent, from the nitrate industry.³ In Costa Rica and Honduras, a considerable share of total current revenue was derived from "tributaciones y regalías" paid by the large foreign companies engaged in the production and export of bananas, and in Colombia from "tributaciones y regalías" paid by the petroleum companies.

Export duties, paid mainly by local producers and exporters, accounted for substantial proportions of total revenue in two countries and for somewhat lower percentages in several others. In El Salvador and Guatemala, duties of this nature, chiefly affecting coffee, provided from about 35 to 12 per cent, respectively, of total current revenue. Since the price of coffee is fixed in a world market on which the two countries in question exert only a relatively small influence, these duties constitute in effect a direct, though unprogressive tax on producers and exporters. The shares of total current revenue corresponding to export taxes amounted to 9 and 14 per cent respectively in Peru and Mexico, where such duties are imposed on a variety of products and are principally paid by local producers and exporters; about

4 to 5 per cent in Nicaragua and Colombia, where again they fall for the most part on local enterprise; and only negligible percentages in Brazil and Ecuador.

Import taxes are a significant source of revenue throughout Latin America, except in Argentina, where in the year under review they provided less than 2 per cent of total current revenue. They are especially important in the Central American Republics and Ecuador, where they alone contributed from about 35 to 60 per cent of current fiscal income, their share greatly exceeding that of export taxes in all these countries. In the remaining countries, the proportion of total current receipts derived from this source varied from about 10 to 20 per cent.

This heavy dependence upon the external sector for revenues has a variety of important effects on taxation systems and economic activities. Firstly, in many countries, tax revenues are subject to sharp fluctuations caused by changes in the world market for one product or for a few commodities. Budgetary instability is thus created which has repercussions on the over-all economy, increasing its vulnerability to external factors. Secondly, these fluctuations influence public investment plans and introduce a strong element of uncertainty into medium- and long-term economic development programmes. Thirdly, the ease or difficulty of obtaining revenue from the external sector indirectly affects tax policy for the internal sector, and thus helps to determine the tax burden, the utilization of potential sources of revenue and the relative importance of direct and indirect taxation in the fiscal system.

Chile and Venezuela, which present extreme cases of dependence on revenue derived from the export of a single key commodity, may be used for illustrative purposes. A break-down of total government receipts from taxation in Chile shows that during the period 1945-55 the external sector contributed approximately 50 to 60 per cent; receipts from copper and, to a much smaller degree, from nitrates, alone accounted for about 30 to 40 per cent. (See table 17.)

² In the case of Colombia and Brazil, the table tends to understate the comparative fiscal importance of the external sector because total revenues given comprise non-central-government revenues, which in Colombia include none and in Brazil only a relatively minor portion of those derived from the external sector.

³ "Tributaciones y regalías" and "derechos de exportación" consist solely of receipts from petroleum in Venezuela and proceeds from copper and nitrates in Chile.

Source: Official statistics.

Chile's fiscal receipts from copper are obtained from income tax paid by the copper companies; from profits on the purchase and sale of foreign exchange accruing from copper shipments; and, in a minor degree, from duties on copper company imports. During the years 1952-54, there was also a tax of 100 per cent on the surcharge, that is, the amount by which the sale price of copper exceeded 24.5 dollar cents per pound; this tax was abolished in 1954 and was more or less replaced by income tax adjustments.⁴

The great extent to which government receipts from copper are vulnerable to sharp fluctuations in the price and demand for this commodity is clearly evident. Such resources declined from 6.3 billion pesos (at constant 1950 prices) in 1945 to 6.0 billion in 1946; they then rose to 9.4 billion in 1948 and fell to 7.7 billion in 1949, after which they increased to 14.7 billion by 1952, but dropped sharply to 9.8 billion in 1953. Since copper has been representing 40 per cent or more, often much more, of Chile's visible exports, receipts from import taxes are indirectly affected by the foreign exchange earned by this metal; these receipts also fluctuate, though over a narrower range than the direct proceeds from copper, and with a somewhat different timing.

The fluctuations in receipts from the external sector are so sharp that they impart a serious instability to total revenue, despite the fact that about 40 to 50 per cent of total current tax receipts are derived from internal taxation which is relatively stable. Aggregate tax revenue has followed a trend roughly parallel to that of receipts from copper, showing one mild, and then two acute declines in the period 1945-53. It fell from 18.6 billion pesos (at 1950 prices) in 1945 to 18.49 billion in 1946; from 24.5 billion in 1948 to 23.4 billion in

1950; and from 31.6 billion in 1952 to 28.3 billion in 1953. These fluctuations have tended to cause or aggravate budget deficits, and have been a key factor in accelerating the marked inflation to which Chile has been subject.

The relation between receipts from petroleum and other current central government receipts in Venezuela, indicates the substantial and ever-growing extent to which revenue is derived from the former source. (See table 18.) The proportion of total current receipts for which petroleum accounted was about 50 per cent in the fiscal year 1944/45, decreased to 45 per cent in 1945/46, and then rose fairly steadily to 61 per cent in 1953/54.

Venezuela derives revenues from petroleum in several ways. There are royalties of 16.66 per cent of the gross value of petroleum produced, plus receipts from the granting of exploration, zonal and other rights; these receipts, which constitute the category "hydro-carbons" in the relevant table, are not strictly speaking tax revenue, but rather returns from government property, since in Venezuela, as in most Latin American countries, the sub-soil, according to the old Spanish law, is public property. Furthermore, there is the income tax paid by the petroleum companies. Finally, there are exchange profits accruing from currency transactions with these companies, which have been grouped in the category "export duties".

The fiscal importance of Venezuela's petroleum industry is still greater than is apparent from the statistics. In the first place, receipts from import duties which, after receipts from petroleum, form the next largest single category, depend to an overwhelming extent on foreign exchange earnings from petroleum exports. Secondly, the level of internal taxation is considerably affected by the influence of petroleum on the creation of income and on the purchasing power of the economy as a whole. Import duties have been accounting for about 15 to 20 per cent of total current receipts, but this proportion has shown a tendency to decline.

Because of the upward trend in the world demand for petroleum, and because this commodity is not subject to fluctuations as sharp as those affecting international trade in most primary goods, Venezuela's revenue from this source seems, for the time being at least, to rest on a reasonably firm basis. It should nevertheless be noted that in the fiscal year 1949/50, when there was a mild recession in the United States and a foreign exchange crisis leading to a general currency devaluation in Western Europe, government receipts from oil in Venezuela were almost 8 per cent less than in the preceding year. Consequently, revenue from import duties also declined. Moreover, potential competition from other petroleum-producing areas should not be overlooked, as well as the possibility that the United States may raise the customs tariff on imports of petroleum, a measure which has from time to time been strongly advocated by the coal industry and other interests. It would not be safe, therefore, to assume that further and perhaps even greater reductions will not take place. The large and growing receipts from petroleum have permitted Venezuela to impose light internal taxation. Despite the fact that *per capita* income in Venezuela is among the highest in Latin America, the ratio of taxes to gross product is one of the lowest. Specifically the levels of exemption

^a Exchange differential.

from income tax are among the highest in Latin America, and the effective rates among the lowest.

The other cases in which fiscal income substantially depends on single export activities are less extreme than those of Chile and Venezuela. In El Salvador, and Guatemala, for example, though export taxes, falling mainly on coffee, represent a large and expanding source of revenue, they do not dominate and pervade all fiscal receipts as occurs in Venezuela and Chile. (See tables 19 and 20.) Receipts from export taxes in the two Central American countries account for a far smaller proportion of total revenue than is provided by those from petroleum in Venezuela. These taxes have not hitherto imparted any general instability to the whole of the fiscal system, such as results from fluctuations in copper receipts in Chile; in fact, during the period covered there was no decrease in receipts from this source in Guatemala, and only a mild decline in El Salvador during 1952. Potentially, however, these taxes, particularly if revenue from them increases in relative importance, are capable of introducing considerable direct vulnerability to external factors into the fiscal systems of both countries.

When a large share of revenue is derived from the external sector through import duties rather than export activities, dependence on the external sector is mitigated, but not entirely eliminated. Fiscal receipts from import taxes are mainly and ultimately, though indirectly, dependent on the foreign exchange earnings from exports; they are therefore vulnerable to fluctuations in exports. Where such receipts account for large proportions of total revenue, as in Central America and Ecuador, this vulnerability is of great potential significance.

The vital importance of the economic structure in determining the degree and nature of fiscal dependence

on the external sector can be seen from a few specific considerations relating to concrete cases. The very heavy fiscal dependence on petroleum in Venezuela is clearly related to the fact that it constitutes a distinct economic sector whose earnings and productivity are outstandingly higher than those of the rest of the economy, the whole of which is subject to its influence. The situation is similar in relation to copper in Chile, although, because the Chilean economy is more diversified, fiscal dependence on copper is less extreme in percentage terms. Employing less than one per cent of the active population, the copper industry has been contributing approximately 7.5 per cent of Chile's gross product. Productivity, in terms of the number of workers employed, is over ten times greater than in the economy as a whole.⁵

The banana industry in Costa Rica and other Central American countries, though it also diverges from the pattern followed by the remaining sectors in the economies concerned, does so less sharply and, probably for this reason, is relatively less rich as a potential source of revenue. In terms of technique, the use of capital equipment, productivity, etc., the banana industry does not constitute so distinct and separate an entity as do petroleum in Venezuela and copper in Chile. The difference between the ways in which the banana and coffee industries are taxed in Central America and the systems elsewhere is related to the disparity in the organization of these industries. Whereas bananas are generally exploited by a few large foreign companies, coffee is produced by many domestic entrepreneurs. Administratively, it is much easier to apply general income taxes to the large banana companies. But, while it is probably by no means impossible, and might, all things considered,

⁵ Copper accounts for about 40 to 60 per cent of Chile's visible exports.

^a Includes revenue from sources other than taxation.

be appropriate to apply them to the coffee producers, the prevailing export duties do offer advantages from the standpoints of simplicity, ease of collection, prevention of evasion, etc.

While the extensive use of import taxes is traditional in most of Latin America, the fact that these duties are much more important in Central America and Ecuador than in the other Latin American countries is also related to the economic structure of the former. The countries in question differ from one another in many significant

ways; but, taken as a whole, and in comparison with most of the rest of Latin America, they are economically undiversified and have a lower *per capita* income. As a result, the tax base is relatively low and this situation places a premium on obtaining revenue from comparatively simple and reliable sources, such as import duties.

Finally, the lesser degree of direct fiscal dependence on the external sector, which is evident in such countries as Argentina and Brazil, is also related to the economic structure. Argentina may be used as an illustra-

tion. The economy there is considerably more diversified and has a greater ability to meet direct internal requirements than that of most other Latin American countries; agriculture is not confined to one or two staple crops and, on the whole, despite the recent decline, it has attained a higher level than in the rest of Latin America; the country thus produces most of its basic foodstuffs, while, in addition, although it lacks coal and is short of petroleum, Argentina possesses a number of industrial raw materials and industry has reached a fairly advanced stage. The monetary sector of the internal economy is well developed and there is not, as in a number of other Latin American countries, a large sector of the population living to a substantial extent outside it. Nor is there a sharp disparity in productivity and earnings between the export sector and the rest of the economy; the former is not dominated by a few large foreign-controlled enterprises but is integrated with the rest of the economy. Although Argentina's exports are not as diversified as those of the United States or the countries of Western Europe, they are somewhat more heterogeneous than those of most of the Latin American countries. For these various reasons, the internal sector of Argentina's economy constitutes a relatively large actual and potential source of government revenue, while, on the other hand, the contribution of the external sector is not particularly distinct or easy of access.

If import duties provide only a very small share of aggregate revenue, this is probably due to the factors noted above in addition to the basic orientation of Argentina's foreign trade and payments. Because other sources of revenue are available, there is little need to rely on import duties for this purpose. Argentina's trade is mainly channelled towards Western Europe, whose trade is generally carried on through systems of exchange controls, bilateral trade treaties and payments agreements; consequently, Argentina's trade policy and payments methods are geared to this type of system. Control of the volume and composition of imports is mainly exercised through the exchange system, which is also used to a considerable extent for protection purposes.

The emphasis given above to the role of economic structure in shaping the tax system is not intended to imply that this is its only, or even, in all cases, its most important determinant. Economic structure is one of the key factors responsible for the general pattern of the tax structures in Latin America. But clearly many other elements—historical, institutional, and political—are also very significant.

Nor is it suggested that the existing tax structures are too much the offspring of circumstance for change and improvement to be possible. The heavy fiscal dependence on the external sector which is characteristic of most Latin American countries is in many respects a serious weakness and tends to make fiscal systems very vulnerable to the vagaries of international trade. Heavy import duties, used to a large extent for revenue purposes, constitute, in the main, a strongly regressive element in the tax system. There is considerable evidence that while a fairly substantial degree of dependence on the external sector is probably inevitable until greater progress is achieved in economic development and diversification, large potential internal sources of revenue generally exist, which, if adequately tapped, could do

much to make the Latin American tax systems more balanced, more stable and more equitable.

3. RELATIVE IMPORTANCE OF DIRECT AND INDIRECT TAXES

An analysis of tax systems with a view to determining the importance of direct and indirect taxation gives some preliminary idea of tax incidence. The study of this incidence and of its economic effects is undoubtedly a much more complicated task, calling for much data which is at present unavailable in most Latin American countries. In the course of future studies such data must be obtained in order to assess this question in greater detail, which is of particular importance for economic policy. In the meanwhile only a very general break-down of the tax structure can be made, on the basis of a differentiation between taxes on capital and income—supposedly paid at the source and practically non-transferable—and others which become incorporated in the cost of the goods and services affected.

In the Latin American countries indirect taxation is of greater importance than direct contributions. (See table 21.) In Brazil, Peru, Ecuador and the countries of Central America (with the exception of El Salvador), the share of indirect taxation in revenue was from 567 to 159 per cent larger than that of direct taxes. In Chile and Venezuela, receipts from direct taxes exceeded those from indirect taxes, but this was due to the contributions of petroleum in the latter and copper in the former case; if these are excluded from the calculation, receipts from indirect taxes prove to have been 273 and 99 per cent greater than those from direct taxes in Venezuela and Chile respectively. In the remaining countries, too, indirect taxes yielded a higher proportion of fiscal income than direct taxes, but the difference was more moderate. In El Salvador, receipts from indirect taxes were 58 per cent higher than those from direct taxes, and in Colombia (without the contribution of petroleum), 32 per cent. In Mexico the difference amounted to 13 per cent and in Argentina to 9 per cent.

The relative importance of the specific indirect taxes varies somewhat among the different countries. As has already been pointed out, import duties form the largest single source of revenue in Central America and Ecuador, and are of considerable significance in the other countries, with the exception of Argentina. Taxes on consumption make a substantial contribution to fiscal income throughout Latin America, and in Brazil they alone provide 40 per cent of the total. Other indirect taxes, including sales, production, and turnover taxes, are of rather less widespread importance than import duties or taxes on consumption. But they account for about 25 per cent of total receipts in Argentina, and for a sizeable proportion in Brazil, Chile and Honduras.

Outstanding among the direct taxes are those on income and exports. Argentina, Brazil and Colombia are noteworthy because around 30 per cent of their current revenue is provided by income tax. The percentage is smaller in other countries and in several cases income tax is of relatively minor importance.⁶

Taxes on inheritance and donations and "other indirect taxes", including taxes on property and capital,

⁶ For a discussion of income tax in several Latin American countries, see section II of the present chapter.

yield quite large proportions of total revenue in Chile, Costa Rica, Colombia, Argentina and Brazil. In the other countries, their share is of only minor significance.

The predominance of indirect taxation in the Latin American fiscal systems indicates a high degree of regressiveness. Indirect taxes are of course not always regressive; their incidence depends on the articles taxed, the relative rates, etc. In Great Britain, for example, purchase taxes are methodically and progressively geared to taxation of luxuries, and taxation of articles of mass consumption is avoided. But the fiscal, i.e., revenue-producing aspect of the British purchase taxes is far less important than their use as instruments for the control of the balance of payments and the general channelling of social expenditure. Moreover, even the most progressive of indirect taxes cannot be as systematically

adjusted to the taxpayer's resources as, for example, direct income taxes. There is a widespread and legitimate tendency to assume that indirect taxes, in particular where their main purpose is fiscal and they account for a substantial portion of total revenue, are, taken as a whole, regressive.

In Latin America, the main purpose of many indirect taxes is, and has traditionally been, fiscal; they have been imposed on articles in common use because these afford an easy source of revenue. Although there are numerous specific indirect taxes which are progressive, or at least partially so, the bulk of the fiscal income is derived from heavily regressive taxes.

Table 22, which presents a break-down of receipts from consumption taxes by articles taxed, for Argentina, Brazil, Chile, Colombia, and Venezuela, indicates that

Table 22. Latin America: Consumption taxes in selected countries, 1953 or 1954

^a Includes 29 per cent of those consolidated taxes on consumption which are levied by municipalities, and on which separate data are not available.

although there are differences in tax classification and in the types of article taxed, there are also certain basic similarities. Consumption taxes in Latin America fall very heavily on cigarettes and alcoholic beverages. There are also taxes on such commodities as matches, toilet and pharmaceutical articles, electric light bulbs, sugar, etc. Finally, there are taxes on petrol, cinema and other shows, luxury articles, etc., but the proportion of consumption tax revenues derived from these is very small compared to that accruing from tobacco and liquors.

Thus in Argentina, from 40 to 50 per cent of total revenues from consumption taxes has been contributed by the tax on tobacco. A further substantial share (in recent years about 25 to 30 per cent) has corresponded to alcohol and alcoholic beverages, including wine and cider, beer, etc. The tax on matches alone has recently been providing a much higher percentage of fiscal income than the tax on luxury articles. There is also a tax on sugar. In Brazil, where consumption taxes have been representing approximately 35 to 40 per cent of consolidated total revenue, over 45 per cent of such taxes was made up in 1953 of those imposed on tobacco, alcoholic beverages and matches.⁷ There are also taxes on certain processed foodstuffs and on numerous articles in common use. In Venezuela, over 90 per cent of the revenue from consumption taxes in the fiscal year 1953/54 was obtained from taxes on liquors, cigarettes and matches, and the remainder from those affecting petroleum derivatives. In Colombia, where a break-down of

municipal consumption taxes is not available, national and departmental consumption taxes on tobacco, beer and matches accounted for over 40 per cent of total consolidated receipts from this form of taxation. In Chile, about 30 per cent of receipts from consumption taxes accrued from taxes on tobacco and alcohols.

The great extent to which taxes on consumption are regressive is clear from these examples. This is especially true of the cigarette and liquor taxes, although the latter, because of the graduated rates for luxury beverages, have a progressive aspect as well. The taxes on such items as matches and soap are not only regressive, but also yield small revenues which probably are often not worth the cost and trouble involved. While there are also many taxes on luxury articles and activities, the total sums derived from these taxes are relatively small compared to those contributed by the clearly regressive taxes, and do not alter the general picture.

A number of countries in Latin America have taxes on general sales, production or business turnover, etc. Argentina and Chile, for example, impose a heavy tax on all sales at the wholesale level of distribution. The states in Brazil have turnover taxes. These general taxes on all sales, transactions, production, and so forth, are severely regressive, though their regressiveness may sometimes be mitigated by the graduation of rates for certain types of transactions.

It is, of course, a commonplace that import taxes may be levied for a variety of purposes, including, among

⁷ Tobacco alone accounted for about 33 per cent.

others, protection of local enterprise, and control of the balance of payments. The lack of systematic and detailed statistical break-downs of receipts from import duties hampers judgment. But it may be stated that in many Latin American countries—for example, in those of Central America—where numerous import duties have traditionally been used to obtain revenues, they constitute in the main a form of tax on consumption, and are regressive. A number of import duties used for protection—in support of a local textile industry, for instance—are also regressive, particularly when account is taken of their effect on local price levels; but of course the need for protection may well be the more important consideration. On the other hand, import duties used to control the balance of payments are often highly progressive, falling most heavily on luxury and semi-luxury imports.

Two specific indirect taxes deserve special mention: those on automobiles and those on petrol. Both these articles may be taxed in a variety of ways, through import duties, sales taxes, those classified as consumption taxes or other forms of indirect taxation. Many Latin American countries tax automobiles, often heavily, and, since their ownership in Latin America is restricted to a relatively small and well-to-do sector of the population, such taxes are progressive.

Numerous Latin American countries also tax petrol and lubricants, though some impose only a low tax, and others none at all. The progressiveness of these taxes is not uniform. They are progressive in so far as they fall on users of private vehicles, and this probably more than counterbalances the fact that they also affect public transport, since they cost the individual owners of private vehicles much more than the users of public transport. The latter, moreover, is sometime subsidized. These taxes, however, often have a heavy incidence on agriculture, trade and other activities, and hence acquire a regressive aspect.

Finally, the weakness in the administration of property assessment, the inadequacy of taxes on property and capital gains, and the frequency of evasion, which occurs mainly in the case of income tax and other direct taxation, adds to the general regressiveness of the existing systems.

In several Latin American countries, there are signs of increasing progressiveness in the tax systems. In Central America, for example, a general income tax was established in Honduras and Nicaragua in 1949 and 1952, respectively, and in other countries reforms of the income tax laws have been introduced since 1949. In several countries these modifications have apparently been bearing fruit. (See again table 21.) In Costa Rica, Honduras and Nicaragua, the proportion of receipts attributable to income tax has been rising; and where, as in Costa Rica, a break-down indicating revenue from the large foreign banana companies and from other sources is available, it shows that the increment is not confined to the receipts from the companies in question. In El Salvador and Guatemala, export taxes are accounting for an increasingly large proportion of total revenue; and while these taxes are not nearly as progressive as income taxes proper, they are more so than the general run of indirect taxes. Mainly because of these higher receipts from income and export taxes, the share of

fiscal income contributed by indirect taxes in Central America has been declining; and, except in Guatemala, the reductions have been substantial.

In Chile, on the other hand, the tax system has been tending to become increasingly regressive. A comparison of receipts from indirect and direct taxes in Chile indicates that whereas total internal direct taxes yielded slightly more revenue than total internal indirect taxes during the period 1945-48, since then the indirect taxes have been making the greater contribution, and there has been a tendency for the gap to widen. Receipts from taxes on personal income have grown at a much less rapid rate than any of the individual categories of internal tax receipts. Those accruing from taxes on the income of enterprises and "other direct taxes", which include taxes on property, capital gains, etc., have increased considerably more slowly than revenue from taxes on consumption and "other indirect taxes". Whereas receipts from income taxes, both on enterprises and on persons, accounted for more than 30 per cent of total internal taxes in 1945, they represented less than 25 per cent in 1953; and, conversely, whereas "other indirect taxes" amounted to less than 25 per cent of total indirect taxes in 1945, they signified about 33 per cent in 1953.

The substitution of progressive for regressive tax systems in Latin America will not be an easy process. Progressiveness is an important *desideratum* in levying taxes, but by no means the only one. Such considerations as the steadiness and volume of revenue and the protection of industry must also carry great weight. Many taxes, even though regressive, may be needed for the revenue they produce, or justified by a legitimate anxiety to protect local economic activities.

Nevertheless, the Latin American countries, as their economies have become more advanced and diversified, have realized the advantage of initiating reforms aimed at achieving greater progressiveness in their fiscal systems, both on grounds of tax equity and because more effective instruments are required for the execution of a far-reaching economic policy. Broadly speaking, these efforts have taken the shape of new direct taxes, or increased rates within the progressive taxation systems already in existence. This is the specific reason why income tax has been introduced in almost all countries during the last two or three decades. There is also a growing tendency to impose heavier taxation on such sources of income or goods as capital gains, real estate, luxury articles, automobiles, petrol, etc., so as to impart greater progressiveness to the prevailing régime. It is patent that a wide field for action exists, whose exploration, barely begun as yet, may lead to a substantial improvement in the region's tax systems.

II. INCOME TAX

1. INTRODUCTION

Since the 1930's income tax has been established in almost all the Latin American countries.⁸ Although in-

⁸ In Brazil, Chile, Costa Rica, El Salvador, Mexico and Peru, income tax was introduced during the period 1920-30; in Argentina, in 1932; in Colombia, in 1935; in Venezuela, in 1942; in Honduras, in 1949; and in Nicaragua, in 1952.

come had previously been taxed to some extent in certain cases, the systems in force had been of a very rudimentary nature. Changes in the individual internal economies, which have created economic groups capable of generating taxable income; the need to increase the efficiency of the fiscal systems as instruments for the mobilization of resources, as well as to offset wholly or in part the decrease in receipts from the external sector; and, finally, the influence of modern ideas with respect to taxation, have all helped to make income tax an important piece of Latin America's present tax machinery.

The stage reached in the evolution of income tax, and the relative size of its contribution to total fiscal income, differ from one country to another on account of historical factors, the lack of uniformity in the levels of economic and social development attained, and the varying length of time this type of taxation has been in force. In Argentina, Brazil and Colombia it accounts for the largest proportion—over 30 per cent—of total

government revenues. Its share is smaller in Chile, Mexico and Venezuela, having fluctuated during the last few years around 25 per cent, and still more limited in the Central American Republics (18 per cent in Honduras, 15 per cent in Costa Rica, 8 per cent in El Salvador, 7 per cent in Guatemala and one per cent in Nicaragua). (See table 23.)

Broadly speaking, although in Latin America income tax is following an upward trend, it represents a far less significant proportion of fiscal revenue than in more highly-developed countries. In the United States, for instance, it provides 76 per cent of public income, in Australia 62 per cent, in England 50 per cent, and in Japan 47 per cent, to cite only a few cases.

A methodical examination of income tax will involve the establishment of a distinction between the contributions exacted from individuals and from corporations, with, in each case, a study of the divergent features of the tax system and of its economic effects.

2. TAXATION ON PERSONAL INCOME

(a) *Types of systems and importance of taxes on personal income*

In some of the Latin American countries—Argentina, Brazil, Chile, Peru and Venezuela—individual contributors are taxed in accordance with a system of schedules, based on a scale of differential rates contingent upon the source of income, and a progressive surtax on global income.

The universal personal income tax with a single progressive rate is found—although with certain variations—in Colombia and the Central American countries. In Colombia, the progressive tax on personal income is accompanied by a surtax on property, which is also progressive, and provides a means of discriminating between income accruing from capital and earned income. In the Central American countries, except for Guatemala, where the incidence of the tax is limited,⁹ the system applied takes the form of a single tax on the contributor's global income.

Mexico supplies an instance of a middle course between the unitary tax on global income and the schedular system. Income is also divided into several categories and schedules, but a different progressive scale is applied for each of these. There is no specific progressive rate affecting the whole of the taxpayer's income from various sources.

Three general questions arise in relation to taxation on personal income. The first relates to the share of total income tax revenue which receipts from this source represent, and recent trends in their participation; the second, to the efficacy of the prevailing systems as a means of collecting funds; and the third, to their degree of progressiveness.

No general conclusions can be reached on the first point, owing to the inadequacy of the available statistics. Nevertheless, in those countries for which data can be obtained, the contributions of the individual taxpayer constitute a large proportion of income-tax receipts in general. (See table 24.) In Brazil, they account for 45.6 per cent of total revenue from income tax, in Argentina for 37.6 per cent, and in Chile for 25.9 per cent. The figure for the last-named country, however, if the taxes

imposed on the large mining companies are excluded, rises to 55 per cent. In Colombia, the tax on persons amounted to 37.9 per cent of total income taxes in 1951.

The evolution of income tax in Latin America during recent years shows no definite trend in relation to the incidence of the tax on individuals and corporations. While in Argentina and Chile a decline in the relative importance of the tax on persons is to be observed, in Brazil the reverse is true. The figures for Colombia do not reveal any clearly defined trend. (See table 25.)

(b) *Level of basic exemptions for personal income*

One of the most serious limitations to be noted in the system of personal income taxes in the under-developed countries is the small number of persons subject to taxation. In India, for example, from a total population of 360 millions, only 2.5 million are affected; in the United States, where taxation on personal income has reached a high level of efficiency, 25 per cent of the population pays income tax.

In those Latin American countries for which data are available, the scope of personal income tax is very limited. In fact, except in Argentina, the proportion of the total population that is subject to progressive taxation is no higher than one per cent. It should be noted, however, that in those countries where the system of schedules is in operation—Argentina, Brazil, Chile, Peru and Venezuela—the number of taxpayers is greater than might appear at first sight, because statistics exclude contributors in the lower-income brackets, who are exempt from progressive taxation but do pay taxes at the proportional rates established in the schedules. (See table 26.)

Table 26. Latin America: Population subject to progressive personal income tax^a

Countries	Year	Population (thousands)	Number of taxpayers	Percentages of total
Colombia	1952	11,844	107,394	0.9

^a Figure subject to revision.

The restricted development of taxation on personal income in Latin America to date, is attributable to several causes. Among these should be mentioned the existence within the various countries of areas that have not been incorporated into the monetary economy; the large proportion of rural population; the low *per capita* income figures—reflected in a high level of basic exemptions—; and, finally, the administrative problems which these factors themselves create.

In order to form some idea of the incidence of income tax, an examination must first be made of the minimum exemption level assessed as a multiple of *per capita* income. A married couple with three children has been taken as a base, and the existing situation in Latin America has been compared with that in other countries.

Table 27 shows the prevailing position with respect to personal exemptions, in accordance with the procedure described. A fundamental difference should, however, be noted; in those countries where a unitary tax

^a In the case of a married couple with three children.

is imposed on personal income, namely, the Central American Republics and Colombia, there is a basic exemption level above which the progressive scale of rates begins to operate. The situation is different in those countries where the schedular system is applied, since here income tax begins as a proportional rate which differs according to the source of income; subsequently, at a higher point in the income scale, the supplementary progressive tax on global income comes into effect.

Exemption policies in Latin America assume two forms. In some countries—Brazil, the Central American Republics, Colombia and Venezuela—a general exemption minimum for the various sources of personal income is applied; others—Argentina, Chile, Mexico and Peru—discriminate between earned income and income derived from investment.

As a rule, the high exemption coefficient in the under-developed countries contrasts with the position in the more fully industrialized nations. While in these latter the individual begins to pay income tax when his earnings are between 2 and 2.5 times as great as *per capita* income, in the under-developed countries the tax comes into operation when the multiple earned by the taxpayer is much higher. This disparity reflects the variations in *per capita* income levels from one country to another, but it is also an indication of the differing degrees of success with which income tax has been fashioned into an effective instrument for the levying of resources.

As regards exemption levels in the various countries, Colombia, El Salvador, Honduras, Nicaragua and Peru represent the highest extreme, their exemption coefficients ranging from 10.7 (Colombia) to 24.3 (Peru); it should be pointed out, however, that in Peru the high exemption level applies to earned income. The exemption coefficients for the nations mentioned nearly approach those recorded for the under-developed countries of Asia.

In an intermediate position, with an exemption limit standing at about 4.8 times *per capita* income, appear Venezuela and Brazil; Costa Rica is not far off, with a coefficient of 6.7.

Finally, Argentina, Chile and Mexico (and Peru as far as investment income is concerned), are those Latin American countries where the exemption limit is lowest in terms of *per capita* income. In Argentina, the coefficient of 3.3 is valid for earned income; as regards unearned income the minimum exempt from taxation is double the figure for *per capita* income, because deductions for dependents are smaller for capital income than for salaries and wages. Earned income in Chile has a very low exemption level, while unearned income is subject to taxation whatever its amount. The depressed exemption limit for earned income is partly attributable to the fact that Chile's intense inflationary process has had a regressive effect on personal taxation, because the taxable minimum legally established in absolute values has never been adjusted to the rise in prices. Nevertheless, reforms have recently been introduced with the aim of imparting a measure of flexibility, by fixing the exemption limit as a multiple of the minimum legal salary, which is periodically readjusted in accordance with the cost-of-living index. The level of exemption for earned income is also very low in Mexico, and income from capital is subject to no basic exemption.

These relationships give an approximate idea of the position of the various countries as regards exemption, but no reliable inferences can be drawn from them on a basis of comparability, in view of the disparities between *per capita* income levels. It seemed useful, however, despite the drawbacks of an analysis in absolute values, to show the exemption limits converted into dollars. (See table 28.)

Table 28. Latin America: Income tax exemption levels in dollars

Note: Conversion rates computed by ECLA were used to convert each country's existing exemption limits into dollars. (See *Economic Survey of Latin America* 1951-52, *op. cit.*, p. 32.)

^a The schedule tax in force in Mexico comprises progressive rates which differ for the various income categories. In the table the exemptions are grouped in the progressive tax column.

The lowest taxable income level in absolute values is recorded for Argentina, Brazil, Chile and Mexico. This confirms the conclusion previously reached when the same problem was analysed in terms of *per capita* income. Next, with an exemption limit lying between 1,000 and 2,000 dollars, comes Costa Rica. In most of the Central American Republics, as well as Peru, exemption is granted up to the 2,000-3,000 dollars income-step. The highest exemption in absolute values for personal income is found in Nicaragua and Venezuela. In Peru and Venezuela the position might appear contradictory, when the values shown in table 27 as exempt from taxation are taken in conjunction with the fact that the exemption coefficients (in terms of multiples of *per capita* income) are 24.3 and 4.8 respectively. Nevertheless, this apparent anomaly may be explained by the marked difference between *per capita* income in these two countries.¹⁰

¹⁰ The foregoing analysis was based on those statistics in table 28 which represent the lowest exemption for each country; consequently, exemption from progressive income tax in countries where the schedular system is in force, and where the smallest exemption minimum corresponds to the proportional tax applied to the various income categories, was not taken into account. A similar procedure was followed in the analysis presented in table 27.

In most of the Latin American countries the absolute exemption limit is below 3,000 dollars, which is the figure registered for the United States; only in Nicaragua and Venezuela is it slightly higher. The relationships described might lead to the conclusion that in the under-developed Latin American countries, with a few exceptions, exemptions for personal income are the same as those prevailing in the United States and in many cases are lower. Such a statement, however, might lead to misconceptions, should other considerations not be taken into account. It is particularly important to pay due regard to what may be called relative exemption; when the exemption limit, expressed in dollars, is similar in the United States and the Latin American countries, in these latter the sum exempt occupies a higher place in the country's scale of incomes. In other words, it does not seem advisable to adopt the exemption minimum prevalent in the United States or in other industrialized countries as a standard of comparison for guidance in the formulation of a taxation policy, since this would imply the exclusion from the sphere of taxation of groups whose income level, in the under-developed countries, is medium or high in relation to *per capita* income.

Despite their limitations, the statistics reveal certain clear and definite facts. Firstly, it is patent that in Nicaragua and Venezuela the exemption minimum is high, in comparison with that of both the other Latin American Republics and the more developed countries; in the case of Venezuela, this characteristic is merely a reflexion of the system of governmental financing, which is largely based on the taxes affecting the petroleum sector. Again, there can be no doubt that in Argentina, Chile and Mexico the existing exemption limit is relatively low. In the second place, in those countries where the schedular system is in force, income tax affects more persons than in those that apply a unitary tax to personal income. This is because, under the system of schedules, exemption ceases at a very low income level and in some instances—Chile, Mexico and Peru, for example—is non-existent where income from capital is concerned. On the other hand, in countries where a unitary tax is imposed on global income, while it is true that the basic exemption limit is higher, the progressive scale of rates is applied as from a lower income level; here Colombia and the Central American Republics provide representative examples. (See again table 28.)

The foregoing analysis has an important bearing upon taxation policy. From one point of view, there would seem to be grounds for establishing the exemption minimum at a reasonably lower income level, since this would be a means of augmenting fiscal revenue and probably of securing more effective instruments wherewith to influence the level and distribution of income for economic development purposes. On the other hand, the existing exemptions are justified as an attempt to maintain the available personal income of the under-privileged sectors at a level high enough to cover the minimum outlays that are deemed essential or desirable. But to confine the present analysis to these statements would mean disregarding other factors, relating to the over-all structure of taxation, which are of the highest importance for the understanding of this problem. In point of fact, indirect taxation also affects personal income. For example, where the taxation system is characterized by the prevail-

ence of indirect taxes, a low exemption limit may increase its regressiveness. Similarly, the effects of a high exemption limit might be counteracted by the consumption tax burden. In the Latin American countries such situations actually do arise, and analyses of the kind described would be essential for the formulation of taxation policy.

The problem of the exemption minimum is also closely bound up with the efficacy and costs of fiscal administration. In many countries it has been argued that the existence of a low exemption limit, and the consequent increase in the number of taxpayers whose income is small, involves the employment of more administrative personnel and implies higher costs which the increment in revenue is not large enough to offset. Although there is much to be said for this point of view, the possibility of improving the productivity of public administration should also be borne in mind. Moreover, even if heavier expenditure had to be incurred, any evaluation of this would have to take into account the whole body of aims pursued by the expansion of the field of taxation, and not only the amount of revenue collected.

(c) *Exemptions applicable to particular types of income*

All income tax legislation includes a series of exemptions designed to serve social ends and to provide economic incentives. An interesting and highly controversial question relates to the inclusion of capital gains under the head of taxable income. On this subject opinions differ from one Latin American country to another. In Honduras and Guatemala, capital gains are considered as taxable income, since all periodic or exceptional additions to the taxpayer's property are defined as income for purposes of taxation. In El Salvador too, capital gains are calculated as income, but are subject to a special tax.

Argentina imposes a proportional tax on capital gains which affects all those obtained from the sale and transfer of goods or real estate; in the determination of taxable income, it is permissible to deduct a part of the purchase cost for every year up to the date of sale. An 8 per cent tax is imposed in Brazil on capital gains derived from transfers of real estate, also with proportional annual discounts. Peru applies a tax with a progressive rate rising from 7 to 15 per cent on the difference between the basic value fixed by law and the sale price. In Venezuela, net profits derived from an increase in the value of real estate are taxed at a rate of 3 per cent. In Chile, Colombia, Costa Rica, Mexico and Nicaragua capital gains are exempt from taxation.

Classic doctrine excludes capital gains from the definition of income because they constitute exceptional and not periodic income. This attitude presupposes a situation of economic stability. It may well be asked whether it is either justifiable or advisable to apply this concept in the Latin American countries, many of whose economies are in actual fact affected by a chronic inflationary disequilibrium which may impart a permanent character to capital gains, if the rise in prices is not confined to a reflection of the devaluation of the currency. Again, during periods of disequilibrium, the ease with which capital gains are obtained may lead to an increase in speculative investment at the expense of

resources that might be used for real capital formation. For these reasons, some countries have studied the possibility of utilizing the tax in question as a reasonable instrument for levying fiscal revenue and for preventing distortions in the structure of investment. Nevertheless, if this principle is put into practice, it raises technical problems; hence it has also met with opposition.

Besides capital gains, another type of personal income which is accorded special treatment under the legislation of a number of countries, is that accruing from the payment of dividends. In Argentina, dividends have to be included in the personal income return, but the law allows that part of the tax already paid through the corporation to be discounted. In Venezuela, income of this kind is exempt from both the proportional and the progressive tax. In these two countries, the prevailing criterion is that to tax both the corporation and the shareholders constitutes double taxation.

Great weight has been attached in most of the Latin American countries to the concept that the juristic person represented by the corporation and the natural persons represented by the shareholders are different entities and therefore must be considered separately for income-tax purposes. Consequently, not only the profits of the corporations, but the dividends received by the shareholders are subject to tax. Thus, in Chile, individuals in receipt of income of this type have to pay a proportional tax of 18 per cent plus the progressive rate corresponding to the supplementary global tax. As an incentive to reinvestment, however, shares distributed in lieu of dividends are exempt from the proportional tax. In Colombia, where dividends used to be exempt from personal income tax, they have been subject, since 1953, to the progressive global rate. In Mexico a progressive tax is paid on dividends under the appropriate schedule, while in Brazil, dividends on nominal shares, although exempt from the flat-rate schedular tax, are affected by the supplementary progressive tax.

Finally, the types of personal income on which exemptions are granted also include income from savings deposits, as well as interest paid by official credit institutions or accruing from national debt bonds. With regard to these last, the aim has been to promote a market for government securities which will permit the expansion and canalization of private savings; in practice, exemption works out as equivalent to an increase in the rate of interest. Experience in this field does not seem to have been very encouraging, save in exceptional cases, as other factors have exerted a stronger influence on the channelling of savings and investment than have the rates of interest alone. Moreover, it should be borne in mind that exemptions of this type may have, alongside their proposed positive effect, a negative repercussion on the tax burden, by enabling the higher-income groups to invest in securities of this kind in order to evade income tax.

Income deriving from social security indemnifications and insurance benefits also enjoys favourable treatment under the legislation of certain countries. Exemptions of this kind are recognized by Argentina, Brazil, and Venezuela. Argentina makes them conditional, in the case of income from insurance policies or pensions, upon the fact that the benefits concerned are payable on account of death or disability.

(d) *Methods of discriminating between earned and unearned income*

In all taxation systems, individual income tax pursues two basic aims: satisfactory adjustment to the capacity for payment of the taxpayers, and differentiation between earned income, income from investment and that from mixed sources. The former objective is achieved

by means of the progressive scale of rates, and the latter through discriminatory rates and exemptions or deductions.

The situation is modified according to the system prevailing in each country. Where the schedular tax is applied, discrimination is exercised by means of differing rates for the various sources of income. (See table 29.)

Table 29. Latin America: Schedular income-tax rates by sources of personal income in selected countries

Source: Income tax legislation.

^a Excluding dividends.

^b Nominal shares. Bearer shares pay 20 per cent.

^c In Mexico, differentiation is achieved through progressive rates for each schedule, except for non-property investment and dividends.

It is in Brazil and Chile that the tax discrimination between investment income and earned income is most strongly marked. In Chile, while the latter is subject to a proportional tax rate of 3.5 per cent, income from non-property investment and from dividends pays tax at rates of 25 and 18 per cent respectively. In Brazil, the differential rates are one per cent and 10 per cent for earned and unearned income respectively; here, dividends are not subject to the proportional category tax and are affected only by the supplementary progressive tax.

In Venezuela, where the degree of differentiation is very slight, the highest rates are those for non-property investment; next come those for income from property and for that deriving from trade and industry. The structure of its taxation system makes Colombia an interesting case within Latin America. As has already been pointed out, the system in use is that of the unitary personal tax with a progressive scale of rates. The means of differentiation is constituted by a supplementary tax on personal property at progressive rates.

In Mexico, where the system occupies an intermediate position between the schedular tax and the unitary personal tax, differentiation between earned and unearned income is secured by means of progressive scales of rates differing according to the type of income, with the exception of dividends and distributed profits, which are subject only to a proportional tax.

The basic factor in discrimination between earned and unearned income is the tax structure. But in certain countries—Argentina, for instance—the method utilized is that of a higher basic exemption limit for earned income. In other cases, like those of Chile and Mexico, special exemptions for earned income accentuate the differentiation already established by the tax rates.

(e) *Progressiveness of taxes on individual income*

The degree of progressiveness of taxes on personal income depends not only upon the scale of rates, but also on the income level above which the tax becomes progressive.

In the Latin American countries, as a general rule, the progressive rate comes into effect at a relatively high income level in most of those countries for which data are available, namely, Brazil, Colombia, Honduras, Nicaragua, Peru and Venezuela. In Argentina, Chile and Mexico, on the other hand, this level is lower. Stress should be laid on the fact that in Venezuela the amount exempt from progressive taxation is over 6,000 dollars, a remarkably large figure in comparison with those registered not only for the other Latin American countries but also for the United States.

The statistics given in table 30 reflect the incidence and progressiveness of taxation on personal income, proportional and progressive taxes being taken together. Broadly speaking, the position of the Latin American Republics as regards the scale of progressiveness lies midway between that of the under-developed countries of Asia and that of the highly-developed nations. Two outstanding exceptions represent extreme cases. Chile has a highly progressive scale of tax rates, similar to that in force in the industrialized countries, especially France; whereas in Venezuela the degree of progressiveness is very slight, even lower than that existing in the countries of the Far East.

Certain conclusions may be deduced from the statistics in table 30 which help to explain why the system of taxation on individual income has advanced so little in the countries of Latin America. In the first place, for the income tax rate to be very high, an income level equivalent to 20 times the *per capita* income must be reached.

Sources: For Latin America, legislation and statistics of the various countries; for the rest of the world, ECAFE, *Economic Bulletin for Asia and the Far East*, Bangkok, November 1953, page 8.

In some countries, such as Colombia and Venezuela, the proportion paid at this level is still very small indeed; in Colombia it is not as much as one per cent, and in Venezuela earned income is taxed at a rate of 2.6 per cent and income from capital at 4.6 per cent. In other countries—Brazil, Mexico and Peru, for instance—when receipts are 20 times *per capita* income, the maximum incidence does not exceed 16 per cent for income from capital; the tax on earned income in these countries is considerably less at the income level indicated. Among the Latin American countries, Chile probably constitutes an exceptional case, since taxpayers whose income is 20 times *per capita* income are subject to a much heavier tax than in the remaining countries; for wages, the incidence is 16 per cent and for income derived from non-property investment, 31 per cent.

Broadly speaking, in the countries of the region, contributors whose receipts are more than 20 times *per capita* income have to pay tax at an increasingly progressive rate. Thus, at an income level of 50 times *per*

capita income the incidence of taxation on individual income is several times greater than on income 20 times as high as the *per capita* figure. Even so, the incidence of income tax at the high income levels is much lower than in the industrialized countries. In most of the countries studied—except Argentina and Chile—the incidence of the tax is less on income 50 times as large as *per capita* income than on income 10 times as great in the industrialized countries. For taxpayers whose income stands 100 times higher than the *per capita* level, the tax incidence is much the same as it is in the more highly-developed countries for an income 10 times bigger than *per capita* income; in some cases, like those of Colombia and Venezuela, especially this latter country, the incidence is markedly lower. It should be noted, however, that the recent tax reforms carried out in Argentina have accentuated the incidence of the progressive scale at the higher income levels. This circumstance is important for the study of the potential sources of income existent in the Latin American countries which might contribute to the financing of their economic development.

Lastly, it should be pointed out that the foregoing analysis relates to the formal incidence of income tax and is based on an example to which the measures adopted in each country are applied. This means that its real incidence may not be the same, if methods of control and administration are defective and leave room for income-tax evasion. Hence, in some cases, although a system may have a highly progressive scale of tax rates, effective revenue is not as large as these rates suggest.

(f) *The schedular tax or the unitary personal tax on income*

Several of the Latin American countries have in recent years expressed their desire to revise and bring up to date the basic structure of income tax, in order not only to improve it as a source of government revenue but also to transform it into an instrument of economic and social development policy. It must now be considered whether the schedular system or the unitary tax on personal income constitutes the more effective means of attaining these ends.

The system of schedules allows of more regular receipts, and offers administrative advantages because it is easier to collect tax on certain income categories at the source; it also arouses less psychological resistance in the taxpayer. Indeed, in this case taxation at the source often enables part of the taxpayer's income to be deducted without his having a clear idea of what sum he contributes. The fact that fiscal policy, by means of differential rates, can stimulate or discourage specific activities, provides another argument in favour of the use of this system. The objection has, however, been raised that in practice it has resulted in a less progressive form of taxation. In countries like Brazil and Chile, where the schedular system exists, the proportion of income-tax revenue deriving from the supplementary progressive rate applied to individual income is much lower than in those where a general progressive tax is imposed on total income. For instance, in Brazil and Chile the proportion in question amounts to 21.8 and 20 per cent, respectively; in Argentina, on the other hand, it is as much as 45 per cent, and in Colombia 38.4 per cent. (See table 31.)

Table 31. Latin America: Progressive tax as a percentage of personal income tax in selected countries

(Millions of units of national currency units at current prices)

Chile ^a	1953	8,267	1,805	21.8
Colombia	1952	281	108	38.4

Source: Official statistics.

^a Excluding the large mining companies.

Clearly, these facts do not indicate that the scale of rates is less progressive in those countries that have adopted the schedular system, but show that the range of individual income affected by the progressive scale is wider in those countries that impose a unitary tax on income.

The need to increase the resources available for financing economic development and for checking or mitigating the inflationary process, may cause changes in the tax system in certain countries to take the form of the establishment of the unitary tax on global income. This is because a progressive over-all régime imparts greater flexibility to the system for levying revenue—an important consideration if, as income rises, a growing share of it is to be channelled towards investment. Such a reform, of course, calls for a major reorganization of the administrative machinery, which is necessarily more complex than under the system of schedules. But one of the advantages attaching to the form of taxation proposed is the experience acquired in the administration of the surtax or supplementary progressive tax on global income. This advantage, however, is only relative, as in most countries where the schedular system prevails, the supplementary tax has not operated very effectively, because the readjustment of methods of control and administration has not kept pace with the growth of total income and the increment in the number of taxpayers. Consequently, it has proved more expeditious to resort to increasing schedular taxes which are characterized by proportional rates and collection at the source.

The basic problem in connexion with the reform of an income tax régime based on a unitary tax on personal income is that of endowing this system with some of the advantages proper to the schedular tax. It seems worth while to study the possibilities of introducing collection at the source for all or for particular types of income, and to spread payment over a sufficient number of periods to secure a regular inflow of revenue without loss of administrative efficiency.

At all events, the establishment of one system or the other constitutes a problem which can be solved only by means of a more thorough study of the taxation system of each country, and in accordance with the special features of the economic and social structure prevailing in each. An evaluation of this kind must be based on three guiding principles: (a) the efficacy of the tax system as a means of transferring resources to the Government, and the degree to which all possible sources of income are tapped; (b) the extent to which the system

encourages or discourages capital formation; and (c) the degree of justice with which the tax burden is distributed among the various socio-economic groups.

3. TAXES ON BUSINESS ENTERPRISES AND INCENTIVES TO INVESTMENT

(a) *General structure of business taxes in the Latin American countries*

The system of taxing business enterprises is determined by the type of régime in force. In the Central American countries business taxes are of a progressive nature; the same is true for Colombia and Peru. The former country imposes an additional progressive surtax on business assets. In countries where the schedular system prevails—that is, Brazil, Chile and Venezuela—the rate is proportional, but in Venezuela corporations are also subject to the supplementary progressive tax. A schedular system with progressive rates is applied to business enterprises in Mexico.

As a general rule, discrimination between the different types of activities does not exist in Latin America, except in the case of agriculture, to which some Governments apply a lower rate of taxation. Some export industries, on the other hand, are obliged in certain countries to pay higher taxes. A case in point is that of Chile, where the income of the large mining companies is more heavily taxed than that derived from trade, industry and other activities. A special example is provided by Venezuela's petroleum industry. The aggregate contributions of the companies concerned are made up of a sum equivalent to 50 per cent of their net profits. When payments on account of other types of taxation (royalties and other dues) have been deducted, the remainder, up to the 50 per cent mentioned, is paid as income tax.

The fact that the system of tax rates applied to business enterprises involves the same treatment for all the different activities, without due regard to the varying degrees of importance of such activities in relation to over-all economic development, has led some countries to consider the possibility of transforming the tax structure into an effective instrument for encouraging or discouraging the movement of resources towards given types of activity. The question has been specifically raised with respect to industry and trade and even to the different branches of manufacturing. As regards trade, it has been suggested that discriminatory taxation might not only produce favourable effects by making other fields of activity relatively more attractive, but might also prove an important instrument of anti-inflationary policy, which could be used to limit the heavy receipts usually accumulated in the trade sector in the course of an inflationary process, and frequently reflected in a higher level of consumption among the groups thus benefited, or a propensity towards luxury investments. In Chile, a bill has recently been proposed which would grant more favourable tax treatment to income derived from industry than to that accruing from trade.

In addition to normal income tax, a tax on excess profits also exists in a number of countries, including Argentina, Colombia, Mexico and Peru. This tax was applied in Chile until recently, but has now been abolished. In Brazil, Venezuela and the Central American

Republics, business is not subject to an excess profits tax. In some countries this tax was introduced during the war as a temporary expedient to mitigate too sharp a redistribution of national income. In others, however, such as Colombia, it has been permanently incorporated into the basic structure of income tax.

The level and structure of the tax rates imposed on business directly influences the organization and size of enterprises in certain countries, apart from the possible effects of the prevailing system of deductions and exemptions.

On the basis of the general principle traditionally accepted, legislation in some countries is aimed at taxing limited liability companies more heavily, so as to offset the advantages they enjoy in the attraction of capital and in the guarantee implied by the fact that they are under State supervision. In Chile, for example, corporations pay a tax of 19.5 per cent, while on the dividends distributed a proportional rate of 18 per cent is charged.¹¹ Where partnerships are concerned, on the other hand, although they are subject to a higher rate—23.4 per cent—the profits of the partners are affected only by the supplementary progressive rate. In Colombia, the differentiation between partnerships and limited liability companies is very marked, as the latter are subject to a heavy progressive rate, while to the former only a small proportional tax is applied. In the other countries of the region the system of taxing business enterprises embodies, either directly or indirectly, means of discriminating between the limited liability company and the partnership, although this does not represent any serious obstacle to investment in the former type of organization.

A careful study of this aspect of the prevailing situation in the various countries may be of great importance for the identification of some of the factors limiting the financing and development of investment. In principle, a less favourable treatment might be accepted for limited liability companies to counterbalance the advantages involved in this type of organization; nevertheless, in some countries the objection has been raised that tax policy, owing to the imperative need for the rapid levying of resources, has brought about reforms in the structure of tax rates, without regard to the resultant danger of excessive discrimination.

A matter of special concern is the way in which heavy taxation on corporations may affect the financing of new industrial establishments. A prospective investor, faced with several similar alternatives, will probably choose the one which does not take the form of a limited liability company, in which case financing may present greater difficulties, as regards both the possibilities of resorting to the commercial banks and the attraction of private saving. From the point of view of attracting foreign capital, there is always the risk that a severely discriminatory régime may not hold out the greatest inducements, since corporations, being under official supervision, offer the best guarantees for the facilitation of association with national capital and for security of investment.

Another aspect deserving of consideration and connected with the over-all structure of taxation on business

income, relates to the repercussions of the system on the size and growth of enterprises. In some countries, the unfavourable treatment affecting limited liability companies handicaps the larger enterprises. In this case, the essential point is the application of a progressive tax on business enterprises. Under the system of progressive taxation on the absolute value of profits, the larger enterprise is more heavily taxed, whatever its rate of profitability may be in relation to the capital invested. As has already been pointed out, this is the system prevailing in Colombia, Mexico, Peru and the Central American countries. In view of the limited information available, no definite conclusions can be reached as to the influence of this method of taxation on the size and growth of enterprises in the countries where it is in force. Nevertheless, in the case of Colombia, where details of the structure are available, this system apparently constitutes a serious obstacle to the organization of limited liability companies and possibly to that of large-scale enterprises.

(b) *Tax policy as an instrument for stimulating and mobilizing private savings*

Apart from its general effect on the volume and composition of investment, income tax may be used to raise the level of savings and to channel resources towards desirable economic activities.

In under-developed countries, particularly in Latin America, steady efforts have been made in the last fifteen years to provide incentives to capital formation within the tax system, mainly through income tax.

Legislation in all countries nowadays includes inducements to attract private savings towards the government securities market, in the shape of total or partial tax exemption for interest payments.¹² In some countries, like Colombia and Chile, the compulsory mobilization of private savings towards either investment in national debt bonds or the financing of specific projects has also been attempted. During the war the Government of Colombia obliged both enterprises and individuals, whose income was above given levels, to invest in national debt bonds. Later, a very efficient method—that of making the purchase of stock issued by the Paz del Río steel mill offset a surtax on income—was applied to finance to the steel making industry. Proof of the purchase of this stock exempts from the tax; otherwise, taxpayers lose the right to acquire the stock and their surtax is considered in arrears.

Compulsory subscription out of private funds exists in Chile, but not to the same extent as in Colombia. While the tax on excess profits was in force, enterprises had to invest in the expansion of their own undertakings or in bonds issued by the Development Corporation. Owing to the low rate of interest on these bonds, the measure resulted only in greater reinvestment. At the present time, industrial and mining concerns are also obliged to invest 5 per cent of their annual profits in housing for workers and employees.

To judge by available information, other Latin American countries have not made extensive use of these methods of mobilizing private savings. Tax policies designed

¹¹ Thus the incidence of the two taxes together on the corporation's net taxable income is 34.2 per cent; furthermore, dividends must be included in the return of global income for the application of the supplementary progressive surtax.

¹² Such measures have already been more fully described elsewhere in the present section.

to promote the reinvestment of savings have generally tended towards more flexible systems of amortization and tax exemption for non-distributed profits.

The utilization of depreciation rates to encourage reinvestment of profits is very important for a policy of financing development. This question, moreover, is closely linked to the inflationary problem in some of the Latin American countries.

In most of these the usual procedure is to calculate depreciation on the basis of purchase cost, the method most commonly applied being that of straightline depreciation. The annual margin allowed for depreciation is computed as a specific and proportional quota, to determine which the value of the amortization unit is divided by the number of years of useful life ascribed to it. Such a system does not favour the expansion of existing enterprises. Consequently, in the last ten years some countries have passed legislation aiming at the achievement of greater flexibility, and authorizing, on given conditions, special and extraordinary amortizations, so as to ensure a larger volume of investment.

In Chile, provision has been made for an additional deduction from taxable income, apart from that normally allowed for amortization and renewal, in order to create a special investment fund exclusively for the expansion of plant and equipment. Moreover, the extraordinary fund may be augmented as the enterprises increase their volume of production; but this additional incentive has proved ineffectual, partly owing to the practical problems involved in determining the increment in the volume of production for the various enterprises.

In Colombia, the taxpayer may apply for an increase in depreciation percentages when the equipment is discarded or becomes useless before the expiry of its probable life-span. Special rates for accelerated depreciation are also allowed when the equipment is in use for more than ten hours daily. In this case, the aim of tax policy is obviously to preserve the capital of enterprises. The second of these provisions, in particular, is very important in under-developed regions, since equipment may be utilized more intensively than in industrialized countries, and the legally-established percentages are based on the experience of the latter.

During the post-war period, as against this system of deductions for extraordinary amortizations, many of the more highly developed countries have used the method known as "accelerated depreciation", as a means of raising the coefficient of the retention of profits by enterprises. Originally this measure was applied to promote the rapid reconstruction of economies ravaged by the war. Accelerated depreciation consists in authorizing higher deduction rates than would be determined by the useful life of the assets; thus enterprises are able to expand production capacity while the amortized equipment is still in use.

No Latin American country has yet set up such a system, although, as previously noted, Colombia does authorize accelerated depreciation, but with the aim of preserving capital when equipment is being worn out rapidly by intensive use. In the context of an economic development financing policy, it seems of vital importance that the countries of the region should study the

feasibility of this procedure, taking local patterns and conditions into account, inasmuch as it might be desirable to replace the present extraordinary amortization methods—sometimes limited and only temporarily effective—by the more general system of accelerated depreciation.

In countries passing through a period of chronic inflation, the problem of depreciation attains greater dimensions. As a rule, the purchasing power of reserves accumulated for the renewal of production assets declines as a consequence of inflation. Where a tax is levied on excess profits, and these latter are calculated in relation to capital that has not been revalued in accordance with the rise in domestic prices, the tax may handicap the financing capacity of the enterprises. Moreover, the increment in the real tax burden involved by this situation may exert an adverse influence on the entrepreneurs' willingness to invest. In Chile, where the rate of capital formation was thus affected, an effort has been made to tackle these problems by means of a system of automatic revaluation of assets, so that profits may be computed on capital values more in line with the rise in prices. To the same end, a 20 per cent increase in the annual amortization quota was allowed in Argentina, in order to offset the increment in high replacement costs.

Another of the measures adopted to promote a higher rate of reinvestment of profits is tax exemption for receipts not distributed by the enterprises. In Mexico, up to 10 per cent of reinvested profits is exempt from the 15 per cent tax on distributed profits; for industry and agriculture, the proportion may rise to 20 per cent. Recently, total exemption from payment of the 15 per cent tax on distributed profits was authorized for enterprises which use accumulated reserves for capital formation. The application of differential and flexible depreciation rates such as those described is interesting as a method not only of creating incentives to the achievement of a higher coefficient of profit retention, but also of promoting the selective allocation of available resources.

In Chile, shares distributed by limited liability companies in lieu of dividends are exempt from the proportional 18 per cent tariff, as long as such dividends correspond to an equivalent amount of capital formation; and in the case of partnerships, those partners who do not withdraw their profits from the enterprise are not liable to the progressive global tax, as far as the reinvested sums are concerned.

Until recently a progressive exemption was in force in Argentina, provided that a minimum reinvestment rate equivalent to 30 per cent of taxable profits was attained.¹³

Among the Central American countries, only Costa Rica and Nicaragua permit special deductions for reinvestment. In the former, up to 50 per cent of income derived from agricultural or stockbreeding activities during the preceding fiscal period may be excluded from the income tax obligation. In Nicaragua industrial in-

¹³ This system was modified during the first months of 1956, and was replaced by another method whereby the amounts invested in expansion of production capacity are deducted from the tax obligation at the following rates: 50 per cent of investments in movable fixed assets, if such investments exceed 10 per cent of the assets concerned at the beginning of the fiscal year; and 100 per cent of investments in agricultural machinery and implements. A 10 per cent deduction is also allowed on the cost of buildings purchased or constructed for production activities.

vestments approved by the Ministry of Economy are deductible.

Although no general trend is apparent in Latin America towards a reform of the tax system which would place a premium on reinvestment of profits and would hamper or discourage their distribution, it is interesting to note that some countries have already adopted new expedients of this kind, involving an approach to tax policy which differs from that prevailing in developed countries. In the latter, the basic problem is how to maintain a high level of employment; taxes are therefore used to prevent an accumulation of savings which is excessive in relation to investment needs. On the other hand, the under-developed countries are faced with a totally different problem: fiscal policy must aim at raising the savings coefficient.

Apart from the efforts made to promote a higher rate of reinvestment, the system of exemptions has been used to guide resources into the channels most likely to benefit economic development. As a general rule, exemptions have been applied with three ends in view (a) to attract resources towards specific branches of the economy; (b) to create incentives for the establishment of new industries; and (c) to stimulate the movement of resources towards under-developed geographic areas. The system has been applied most extensively in connexion with specific sectors, especially those where private enterprise and capital were not in a position to achieve satisfactory development. Effort has been particularly concentrated on attracting capital towards the financing of basic industries and the building of low-cost housing.

In 1940, a programme of incentives to manufacturing and agricultural development was initiated in Colombia through tax exemption for specific branches. In some cases, the privilege depended on specific conditions relating to the production capacity and employment level of the enterprises claiming it. These measures, however, did not constitute a very great inducement, partly because monetary expansion and the difficulty of importing equipment during the war rendered other economic fields, especially investment in real estate and financial undertakings, more alluring and accessible. During the post-war period, exemption policy was focused mainly on the development of the steel making industry. Recently, after the Paz del Río steel mill had entered operation, measures were adopted to ensure an internal market for its finished products. Thus, enterprises utilizing more than 80 per cent of domestic iron and steel as raw materials are exempt from taxation. In recent times, Colombia has also offered incentives to the production of electric energy, according private capital the same favourable treatment as the official power companies.

In Chile, the tax policy has also created inducements for the development of certain nationally desirable activities: low-cost housing projects; investment in the planting of artificial forests; the fish and shell-fish processing industry; transforming industries manufacturing mining equipment; and the iron and steel making industry. In

the last named instance, tax privileges are granted only to those Chilean concerns of whose capital at least 60 per cent is subscribed by Chilean nationals or corporations.

Tax exemptions have become an important part of the Mexican Government's policy since 1941, when a law was passed granting five years' tax exemption to such industries as were considered necessary for the country's economic development. In 1946, this law was replaced by another which set up three groups of eligible industries, and extended the original duration of the privilege.

The Colombian Government has accorded tax exemption to enterprises established wherever climate, health or transport conditions have prevented the incorporation of the areas in question into the national economy. Concerns operating in certain northern provinces of Chile, or in the far south, are also subject to a tax treatment involving partial, or in some cases total, exemption from income tax, on condition that a given minimum percentage of domestic raw materials be utilized.

In addition to specific exemptions, many countries take more general steps to encourage the installation of new industries. The efficacy of such measures may, however, be restricted by two important factors. In the first place, the concept of new industries sets up very narrow limits, since it includes only those enterprises which manufacture goods not already produced in the country. Thus, even when additional capital is required in many branches of production, exemption is not granted simply because there is an industry of the same kind already in operation; conversely, the privilege promotes the establishment of other, less necessary industries, merely because they do not as yet exist. The second reason for the relative inefficacy of the legislation described is that, in order to claim exemption, new industries must utilize domestic raw materials either entirely or in excessively high and inflexible proportions. The purpose of such measures is clearly to stimulate demand and thus promote the development of domestic industries producing raw materials—a highly desirable target for a development policy—but it would perhaps be more reasonable and realistic to introduce a greater degree of elasticity.

Lack of data makes it difficult to assess the concrete effects of tax exemption policy on capital formation and the channelling of resources. It is safe to assume, however, that the measures adopted in this field have been of positive aid to the development of the iron and steel industry in Colombia and Chile; moreover, in the latter country they have been successful in promoting the establishment of low-cost housing enterprises. In 1949-54, fiscal exemptions for industrial development in Mexico amounted to 681.1 million pesos, of which 261 million represented income tax. Statistics show that during the period 1940-55, 851 Mexican industries, of which 533 manufacture capital goods and 318 consumer goods, were benefited by tax exemption. The creation of these industries, in their initial stages, involved the employment of 69,974 persons.

Chapter III

PUBLIC SAVINGS AND DEFICIT FINANCING

I. INTRODUCTION

The post-war growth of the public sector in Latin America has been accompanied by accumulated budget deficits which in almost all countries have tended to exceed occasional surpluses and which in some have had profound inflationary repercussions. This trend is a result of the disparity in the growth of government revenue and expenditure. That of fiscal revenue has been irregular and strongly influenced by fluctuations in exports and in the level of economic activity; government expenditure has tended to expand more steadily throughout most of the post-war period.

This disparity is manifest in the marked fluctuations which can be noted in public savings. In certain countries these have even been negative in some years, signifying that current outlays alone have exceeded ordinary revenue; but in most Latin American countries public savings coefficients have generally been superior to those of the respective economies as a whole.¹ Although public savings have not shown any general tendency to improve in relation to fiscal income, in a number of republics they have risen impressively in comparison to both current government expenditure and the gross national product.²

On the basis of this comparison, the countries of the region can be divided into two groups: those where fiscal income and savings have risen more rapidly than national income; secondly, those where no such increase has occurred, or where the former have definitely lagged behind the latter. In most of the countries where the relative importance of fiscal income and savings has grown (Mexico, Colombia, Venezuela and some of the Central American Republics), public investment has expanded very substantially and has contributed significantly to the relatively rapid rate of economic growth recorded by these countries. The opposite tendency can be observed in Argentina and especially in Chile, whereas in Brazil public investment has tended to fluctuate considerably and the contribution to economic growth has in large measure been a result of its contra-cyclical timing. An aspect common to most of the Latin American Republics has been the important and at times decisive role played by the external sector in determining these trends.

Not only those Governments handicapped by a lag in revenue and savings but also those which have been favoured by a large expansion have had recourse fre-

quently or even systematically to deficit financing. The methods used to finance budget deficits vary widely from one country to another, but in general it has been difficult to cover these deficits completely without resorting directly or indirectly to the issue of new money. Such inflationary financing has naturally been on a larger scale in the republics where fiscal income has not grown or has tended to lag in relative terms; under these circumstances, government finances have at the same time been one of the major victims and one of the principal contributors to a vicious inflationary circle.³

As a result of these trends, public debts have risen, but the increment has generally been smaller than might have been expected from the size and persistency of fiscal deficits, and the relative importance of debt service payments, has almost universally declined. There are several causes of this apparent discrepancy, one of which is the tendency towards a greater increase in floating rather than consolidated debts and the recourse to the issue of new money. This method of financing adopted by some Governments does not enlarge the recognized public debt as much as more orthodox methods and seldom gives rise to service payments. Public bonds, on the other hand, have not found a receptive market and are usually closely held by official financial institutions. Therefore, debt management has in general favoured an excessive expansion of the means of payment and has consequently impeded the effective implementation of monetary and fiscal policy.

The increase in the external debt has been distributed very unequally among the countries of the region and has been accounted for mainly by credits to decentralized investment institutions rather than to governments. It has also been associated more closely than in the past with foreign exchange problems, particularly those arising from general balance-of-payments disequilibria. Thus, of the post-war rise in the region's external debt, Brazil is responsible for approximately three-fifths, most of which is attributable to payments difficulties and is payable over a relatively short period of time. Service payments in such cases represent a serious burden on the future capacity to import, but the majority of Latin American countries are still in a position to absorb a substantial increase in their external debt obligations, provided that such obligations are well distributed as among long-term, medium-term and short-term debt.

¹ The term public savings coefficient is applied to savings as a proportion of fiscal revenue, while the coefficient of the economy as a whole represents total savings as a percentage of national income.

² All the statistical series in this chapter are expressed in current values, unless otherwise indicated.

³ Owing to the difficulties of evaluating the inflationary impact of government finance, no attempt will be made in this chapter to quantify the contribution of the public sector to inflation in Latin American countries. To do this, it would be necessary to analyse thoroughly the composition of public revenues and expenditures in order to judge whether the income-generating effect of government outlays was larger or smaller than that which they would have had if spent instead by the taxpayer. In cases where the inflationary impact of fiscal policy is apparent, this will of course be pointed out in the text.

II. GOVERNMENT SAVINGS

Government savings are defined as the difference between ordinary revenue and current expenditures. These are the funds that are available to finance public investment. Since one of the objectives of Latin American Governments is to raise the rate of capital formation, the public savings coefficient could logically be expected to be larger than that of the private sector so as to increase the coefficient for the economy as a whole. It should not be forgotten, of course, that public savings are often subject to rather broad fluctuations, since they represent the net difference between anticipated revenue

and projected expenditures. Tax receipts are quite sensitive to changes in the level of economic activity, and especially to changes in the value of exports which directly or indirectly provide a substantial proportion of total fiscal revenue in most Latin American countries. Adjustment of budgeted expenditures to altered revenue prospects, on the other hand, usually follows with a lag. Statistics on public savings coefficients in Latin America confirm both of these observations. (See table 32 and figure II.)

More striking than fluctuations within any one country are the very great differences in the public savings coefficient from one country to another. At one extreme

is Argentina, where the public sector has dissaved in three out of nine years and the coefficient has not exceeded 12.5 per cent in any year.⁴ At the other extreme is perhaps Venezuela, where since 1947 the savings coefficient has remained relatively high and has moved within a narrow range of 35 to 40 per cent. The latter country has enjoyed a large and stable fiscal revenue from exports, and the rise in the price level has been moderate. In most countries where variations in the savings coefficient have been large, the main cause can be traced either to the external sector or to internal inflation, or to both. It is interesting to note, however, that in no country is any prolonged trend noticeable in the size of the coefficients, with the exception of Argentina and Chile, where a marked decline is registered over recent years.

Since public savings are a function of fiscal revenue and current expenditure, a comparison of the relative growth of these items in relation to the gross product of each country should indicate the main sources of the variations observed in the savings coefficients. On the basis of such a comparison, the countries of Latin America can be divided into two groups. In the first group

⁴ In no country have social security institutes been included in the public sector, but this is especially important in the case of Argentina, where funds from these organizations have been used to finance most of government investment in recent years. This is a question which will be taken up later. Therefore, the inflationary effect of public finances in Argentina has been due not to the deficits of the central government but to the operations of other public entities, as will be seen later.

appear Argentina, Brazil and Chile. Public savings coefficients have tended to decline in Argentina and Chile, as current expenditures expanded more rapidly than fiscal revenue. (See table 33.) Since 1947 current outlays of the Argentine Government have also grown much faster than the gross product; the latter, in fact, barely increased in real terms. In Chile, on the other hand, the growth of current expenditure has not exceeded the rise in the gross product during the post-war period as a whole, although such a tendency was noticeable during the years 1950-53. The decrease in public savings has arisen less from an attempt on the part of the Chilean Government to gain a larger participation in the gross product, as is apparently the explanation in the case of Argentina, than from a serious lag in the growth of fiscal revenue. From 1949 to 1954, both current government outlays and the gross product in Chile rose by 400 per cent, whereas ordinary revenue expanded by only 270 per cent, or in exactly the same proportion as the price level. This lag in fiscal income is associated both with fluctuations in receipts from the large foreign mining companies and with inflation.⁵ The Chilean Government has as a result received a declining share of the economy's total real resources to finance a rising burden of fiscal responsibilities.

⁵ The policy of selling foreign exchange at preferential rates to subsidize essential imports has also been an important cause of the slow rate of growth of fiscal revenue in Chile. It has been estimated that between 1950 and 1952, if the Government had sold this exchange for a price closer to its real value, it would have increased fiscal income by an amount larger than the public deficit during these years.

^a The indices given in the table are not comparable on an inter-country basis, as the effect of the rise in price levels, which has varied greatly from one country to another, has not been eliminated. Different base years have therefore been used, according to the statistics available, and in the case of Argentina and Costa Rica, in order to avoid the years 1945-1946, when savings were negative.

^b These figures are negative.

^a See note ^a to table 33.^b These figures are negative.

The growth of federal government income, current expenditures and the gross product in Brazil was remarkably similar between 1947 and 1954; all three indices have expanded by about 225 per cent, in comparison with a 20 per cent rise in prices. It can be seen in table 34, however, that there was some lag in fiscal revenue up to 1950, which kept public savings from rising; but this situation was corrected by a policy of budget economy in 1951-52. As from 1955, a basic mal-

adjustment has appeared in federal government finances, principally as a result of substantial upward salary revisions, which have sharply raised current expenditure and contracted public savings. The current income and expenditures of states and municipalities in Brazil, unlike the Federal Government have expanded considerably more rapidly than the gross product. This increase in both income and outlays has been rather similar, however, so that savings coefficients have not been affected

adversely except in 1952, when they fell to only 7 per cent for states and municipalities combined.⁶ (See again table 32.)

Table 34. Latin America: The expansion of real fiscal revenue compared with the growth of current expenditures and the gross product in selected countries

(Percentage changes at constant prices)

	Gross product	Current expenditure	Ordinary revenue
Venezuela (1945-53)	93	107	173
Colombia (1945-54)	87	162	190
Mexico (1945-54)	56	90	105

Source: Official statistics.

The second group of countries is composed of those in which the growth of ordinary revenue has surpassed that of current expenditure, and both have increased substantially more rapidly than the gross product. The result has been that public savings have expanded not only absolutely but as a percentage of the gross product, though not as a proportion of total fiscal income. This is the situation that might be expected in a developing country, where the public sector is obliged to increase its participation in national income in order to allocate a rising share of total real resources to capital formation. The countries for which information is available and which fit into this group are Colombia, Mexico, Venezuela and some of the Central American Republics.

In Colombia, Mexico and Venezuela—where statistics are more reliable and complete—the expansion of ordinary government revenue has been impressive even when compared in real terms with the growth of the gross product. (See table 34.) Fiscal income has grown about twice as fast as the gross product in these countries in spite of a large increase in the latter; and the margin between revenue and current expenditure has been substantial, especially in Venezuela. A similar trend can be observed in most of the Central American countries under consideration, although apparently with less uniformity.

The favourable situation of these countries has been due not so much to internal factors as to the contribution of the external sector. The role of petroleum in Venezuela has already been referred to above. In El Salvador, Guatemala and Nicaragua, where export activities also provide a large share of fiscal income, the swift rise in ordinary government revenue began in 1950 and was related directly to the sharp improvement in the terms of trade for coffee. The same factor was mainly responsible for the strong expansion in the revenue of the Colombian Government beginning in 1950, when the relative contribution of internal taxes began

⁶ Since current expenditure of local governments may be somewhat underestimated, it can be stated that in general these governments have saved a smaller proportion of their income than the Federal Government. The fact that they have not been willing to invest a lesser share of their revenue has raised serious problems which will be discussed below. States and municipalities have been considered separately from the Federal Government in this chapter, since together they are as important as the latter in the public sector of Brazil.

to decline. In Costa Rica, export taxes also contributed to the sudden rise in fiscal income, due in part to the new tax levied on the banana companies as from 1949; but the rise in import duties was the main contributing factor.⁷ In Mexico the greater increase of government revenue over current expenditure and the gross product also began in 1949, as a result of larger export tax receipts following upon the devaluation of 1948.

The above analysis thus leads to the conclusion that the external sector has been the decisive factor in determining the evolution of public savings in those countries of Latin America which have been favoured by growing or relatively high savings coefficients.

In Chile the external sector has also played a very important role in the decline of public savings.⁸ In Argentina and Brazil, on the other hand, it does not contribute a large share of fiscal revenue. This very situation, however, is responsible for the fact that in Brazil the Federal Government did not benefit from the sudden improvement in the coffee terms of trade in 1949-50, since exports are not taxed to any appreciable extent in this country; and the indirect participation of the Government in the greater income generated by the improvement in the terms of trade was weakened by the fact that planters in Brazil are able to evade to a great extent the payment of income taxes. In Argentina, although the stagnation of exports has undoubtedly affected government income indirectly, the main cause of the decline in public savings was the considerable expansion of current expenditure, which was not matched by the moderate increase in revenue.

It is now necessary to analyse to what extent the benefits of the export boom have been sufficient to cover public investment and how far these countries with stable or declining public savings have had to resort to deficit financing.

III. BUDGET DEFICIT

Government budget deficits or surpluses are defined in this study as the difference between public savings and capital expenditure.⁹ Given the fact that investment expenditure is fixed by the autonomous decisions of Governments and that savings are somewhat volatile, it is logical to expect that sporadic budget deficits will occur if public authorities attempt to raise their investment to the maximum and maintain the continuity of public works. (See again figure II.) It is difficult to

⁷ Although official statistics of Honduras show that the sharp rise in government revenue beginning in 1949 came mainly from larger internal direct tax receipts, these in reality also originated from larger income taxes paid by the banana companies.

⁸ Although internal factors connected with inflation were also important in Chile, it is interesting to observe that fluctuations in fiscal income are closely correlated with variations in tax receipts from the large mining companies, and that the depressing effect of a decline in exports was reflected in internal tax receipts after a year lag.

⁹ Budget surpluses or deficits can also be defined as the difference between current fiscal income and expenditure, so that they would be equal to public savings or dissavings. In this study the definition given in the text has been preferred because it corresponds to the concept employed by Latin American Governments in the presentation of statistics on public finance and because it represents that part of total expenditure which must be financed by credit or by the issue of money.

contract or expand capital outlays in exact conformity with the annual fluctuations in public savings. As was pointed out earlier, a reasonable expansion of the public debt to finance worth-while projects is justifiable provided it is financed by the transfer of real resources from the private to the public sector, or by foreign loans. Budget deficits or surpluses can also be an important tool of

fiscal policy in maintaining the level of economic activity, or in offsetting the effect of changes in the level of private investment on the rate of capital formation.

If budget balances are expressed as a percentage of ordinary revenues (see table 35), far less uniformity exists among the countries of Latin America than was found in public savings coefficients. (See again table 32.)

Of the countries with growing or relatively large public savings, Venezuela shows rather small surpluses and deficits which have almost neutralized each other over the period as a whole. Such is not the case with the other countries in this group (Colombia, Costa Rica, El Salvador, Guatemala, Mexico and Nicaragua), although the favourable impact of external sector revenues in 1949-50 is still quite visible in most of them. In general, up to 1949-50 budget deficits were rather large or increasing, after which they fell sharply or disappeared. (See again figure II.) In at least one case (Costa Rica), a large share of the increase in fiscal income was used to accumulate budget surpluses in order to retire a portion of the previously accumulated public debt.

Public investment expenditure of the countries mentioned as having been favoured by a large rise in external sector receipts in 1949-50, increased from two to three times between 1949 and 1952.¹⁰ (See again table 33.) This investment was much greater than that experienced by the other Latin American republics and gives an idea of the extent to which the expansion in public investment in the region has been related to trends in export activities. The rate of increase in public investment was so rapid, in fact, that budget balances again became less favourable, and in several countries sizeable deficits were accumulated. After 1953 external events were again decisive in determining trends in budget balances, although the experiences of the different countries varied considerably.

¹⁰ In Nicaragua, the increase was fivefold and in Guatemala less than 50 per cent. In the latter country, trends have not conformed to the pattern noted in the text. Before 1950 budget deficits amounted to between one-third and one-half of ordinary revenue, which was growing at a relatively slow rate. Since 1950 the Government has apparently preferred to employ larger revenues in a reduction of these deficits rather than in a substantial expansion of expenditure.

Figure II

LATIN AMERICA: GROWTH OF PUBLIC INCOME AND EXPENDITURE IN SELECTED COUNTRIES

(Current value in national currency)

Semi-logarithmic scale

Towards the end of 1953, the terms of trade of coffee again improved very substantially, resulting in a sharp increase in the public revenue of Colombia and the Central American coffee-exporting republics. Statistics for the latter countries are incomplete for 1954, but it can be observed that in El Salvador successive deficits were converted into a budget surplus during 1954 in spite of a 15 per cent expansion in public investments in this year. (See again tables 33 and 35.) The Colombian Government, on the other hand, followed a policy of increasing expenditure to the full extent of the higher revenue, so that no reduction in the budget deficit took place in 1954, although it did not increase. As a result, since 1945 real public investment has risen by 175 per cent in Colombia, an increase which is considerably greater than in any other major Latin American country for which information is available. This expansionist policy led to a dilemma in 1955, when the value of coffee exports declined as rapidly as it had increased during the previous year. A contraction in public expenditure, to conform to lower tax receipts, would have depressed the level of domestic economic activity; the Government thus adopted a policy of maintaining purchases of coffee stocks from growers and of neutralizing, by means of credit and public expenditure, the deflationary effects of the disequilibrium in the balance of payments. As a result, a considerable budget deficit was probably incurred and special measures had to be adopted to correct the trade deficit, including exchange depreciation, the implementation of a limited system of multiple exchange rates and the reimposition of a list of prohibited imports.

An opposite contra-cyclical policy was followed in Mexico. In order to combat growing budget deficits and a balance-of-payments disequilibrium, the Government reduced expenditure in 1953, but revenue fell even further as a result of the decline in economic activity. Consequently, expenditure was raised towards the end of the year at the cost of a greater deficit; but the apparent effect of this policy was to increase the liquidity of the economy, a development which put even more pressure on the balance of payments. In 1954, the Government was obliged to resort to the same policy as had been adopted in 1948, namely, considerable devaluation accompanied by heavier export taxes. Although the government deficit was even greater in 1954, the large increase in public revenue during 1955 was again sufficient to avoid a fiscal deficit and to balance foreign payments.

In Brazil, fluctuations in the budget balances of the Federal Government have been due mainly to changes in investment expenditure. These outlays grew very rapidly up to 1950 under the stimulus of the SALTE Plan, but the large deficits during the last two years of the period in question obliged the Government to adopt a policy of strict budget economy. Consequently, between 1950 and 1952 investment expenditure did not increase in spite of a 40 per cent rise in the price level during this period, and budget surpluses were accumulated in both 1951 and 1952. This policy turned out to be compensatory. The period of expansion in public investments coincided with a very slow upward trend in private capital formation, whereas after 1950 the increase in the terms of trade and the level of imports stimulated a marked recovery in private investment, which was accompanied by considerable inflationary pressure.

After 1952, the Federal Government again shifted to a policy of increased capital outlays, which as before outgrew public savings and brought about new deficits. These deficits were injected into an economy in which the aforementioned inflationary pressures had not subsided, and they coincided with the progressive devaluation of the cruzeiro which began with the exchange reform of 1953. By 1955, wage adjustments of public employees had so increased current expenditure, that although federal investment outlays probably did not increase in this year, the deficit amounted to approximately 8 billion cruzeiros, or over 13 per cent of total ordinary revenue.

Throughout the post-war period the finances of local governments have tended to disorganize fiscal policy in Brazil. Mainly as a result of the policy of a few of the large states, the budgets of these governments have shown an annual deficit which in only two years has amounted to less than 10 per cent of the total revenue of states and municipalities combined.¹¹ Thus, even when the Federal Government was following a policy of budget economy, the effect was largely or completely offset by local government deficits; and deficits suffered by the former were reinforced by those of the latter with serious inflationary consequences.

In Argentina and Chile, fiscal deficits in recent years have been caused more by the decline in public savings than by increases in government investments. In Argentina, large deficits have been recorded in every post-war year. Nevertheless, since 1948, capital outlays have not only lagged behind the rise in the gross product but they have actually decreased in real terms. But since public savings have become more and more negative, not only these moderate investments but even a part of current expenditure have had to be financed with credit. In this respect, it is interesting to compare the evolution of public investments with the relative size of fiscal deficits. (See again tables 33 and 35.) Capital outlays have really increased only twice during the period 1945-53, once in 1948 and again in 1951. During the first two periods of stable investment—1945-47 and 1948-50—the relative importance of the deficits tended to decline; but after 1951 no such trend was noticeable, owing to the accelerated growth of current expenditure and the consequent decrease in public savings.

In Chile also, public investment has tended to lag behind the growth of the gross product and the rise in the price level. Until recently, however, budget deficits have been relatively smaller than those of Argentina, and in 1948 and 1949 the Chilean Government budget even showed moderate surpluses. It is interesting to observe that these surpluses were made possible by the restriction of public investment during these years. This policy coincided with the export recession of 1949, however, and in 1950, the Government decided to expand expenditure considerably, despite a lag in ordinary fiscal receipts during this year, in order to compensate the effect on the level of economic activity. Since then, with the exception of 1952, the state of public finances has tended to deteriorate progressively as the rate of inflation has gained momentum.

¹¹ The figure for 1955 is a budget estimate only, and is almost certainly too low.

IV. THE MECHANISM OF DEFICIT FINANCING

There are three ways of covering a budget deficit: (a) with cash balances accumulated from the surpluses of previous fiscal years; (b) by borrowing, or (c) by the issue of new money. Except in the case of Venezuela, the use of the first method has been limited by the fact that deficits have tended to exceed surpluses by a fairly wide margin in most of the other Latin American countries, so that the other two methods have played the most important role. Public borrowing—the kind that represents the transfer of real savings from the private sector or credits from abroad—depends on the availability of loanable funds. Since foreign credits have not been available during the post-war period to finance general public works or budget deficits, Governments (as distinct from semi-autonomous investment institutions or public enterprises) have had to draw mainly upon internal resources to finance their deficits. Securities markets in Latin America are not very highly developed and their capacity to absorb new public bond issues is strictly limited. The banking systems do not usually possess large excess reserves, and their purchases of long-term bonds are restricted by their stringent investment requirements. Since Latin America is a capital-shortage area, the price of money is quite high, so that private financial institutions do not voluntarily purchase more than the minimum of low-interest-bearing securities essential for the diversification of their portfolios. Furthermore, if inflation exists, investors naturally prefer stocks with a variable rate return and offering the prospect of capital gains.

The above considerations in themselves are sufficiently weighty to demonstrate that only relatively small amounts of public bonds are likely to be purchased voluntarily by the private sector. But there is the added problem that budget balances tend to fluctuate violently in Latin American countries, so that the demand for credit on the part of Governments is very unevenly distributed over the course of time and usually bears no relation to the availability of loanable funds. The severity of these fluctuations can be appreciated from table 36, where fiscal surpluses or deficits are compared with total capital expenditures. Although Argentina and Chile are extreme cases in which a part even of current expenditure has had to be financed by credit at times, in all other coun-

tries at least half of total investments have had to be so financed in some years.

This situation explains why public authorities have had to show a good deal of ingenuity in finding ways to promote the sale of public securities, and why, failing to cover the full amount of the deficits, they have so often had to resort to measures which directly or indirectly result in the issue of money. It is important to understand how the mechanism of deficit financing has operated in Latin America, although no attempt will be made in this study to give an exhaustive description for each country. A few salient examples of the different methods will suffice. In general, these methods can be divided into three types: (a) special incentives to encourage the voluntary purchase of public bonds; (b) the obligatory purchase of securities, and (c) the creation of money.

It must first be asked what are the features of a security that most appeal to the investor. The answer is safety, liquidity and an attractive rate of return. Public bonds cannot usually compete with private stocks in the latter respect, since there are often legal restrictions on the maximum rate of interest that can be paid, and the burden of public debt servicing must be kept down to a minimum. However, in Chile it has been suggested that adjustable bonds be issued, bearing an interest which varies with changes in the cost-of-living index. This is a proposal which is of course related to the question of security against a loss of purchasing power as a result of inflation. In Brazil, however, some states have in recent years been in such need of credit as to have been willing to sell bonds at so large a discount below nominal values that the effective rate of return has in certain cases amounted to more than 20 per cent, even though an existing usury law makes 12 per cent the maximum interest rate that can legally be charged. Aside from these somewhat exceptional examples, there are other methods which have been used more frequently to increase the remunerativeness of government bonds, such as exemption from taxation or advance payment of interest.

Normally, however, public authorities must endeavour to make the security and liquidity of bonds so attractive that they outweigh the disadvantages of a low fixed rate of return. If a country's currency is unstable or

there is a prospect of devaluation, one method of assuring securities is to make them payable in a foreign currency. The drawback of this method is that if a country's currency is under pressure, it is usually suffering from balance-of-payments difficulties, and the payment of additional debt services in dollars only aggravates these and deepens distrust in the stability of the national currency. Where there exists full confidence in public finances, or in the project to be financed, a government guarantee is often sufficient to assure the successful floating of a security, as in the case of the Avenida Bolívar in Venezuela or the Rio Lempa project in El Salvador. These are examples of issues made by semi-autonomous institutions, and it is interesting to note that in general such issues have been accorded a better reception by the public than long-term government debt bonds.

Of the many methods employed to give liquidity to public securities, the most common are those that make them freely negotiable or discountable at central banks. In a number of countries there exist special institutions which buy and sell official bonds in the open market in order to regulate their value. If the bond market is very small, however, it usually occurs that the regulating bodies are themselves the main bondholders, so that in effect the Government purchases bonds from itself with fiscal resources or with bank credit. This is apparently the case in Ecuador, for example, where there exists a Fondo de Regulación de Valores which receives allotments from the government budget, a part of customs receipts and a share of central bank profits to finance its operations. It has been proposed that this institution be replaced by a Comisión de Valores empowered to issue bonds in foreign currencies in order to attract private capital, which would be devoted entirely to economic development projects and not to financing general budget expenditure as at present. In Mexico, the Nacional Financiera plays a very important role in regulating the securities market, and in this case the institution has not overloaded its portfolio with public bonds.¹² Furthermore, most of the funds of the agency are provided by so-called "certificados de participación", which have been sold mainly to the public and represent real private savings.

The high liquidity of government bonds is of course a potential threat to the solvency of the institutions responsible for their regulation and to the effective implementation of monetary and fiscal policy. At any moment speculative selling may take place precisely when the Government wishes to reduce the liquidity of the economy or when it requires substantial new credits itself. This occurred in Mexico in 1954, when a wave of selling preceded the devaluation, with the result that the Bank of Mexico was obliged to use its own resources to absorb a very large amount of government securities. The money thus placed in circulation was largely remitted abroad and consequently exercised a heavy pressure on the already adverse balance of payments.

In Brazil, a measure designed to give liquidity to public bonds resulted in serious financial difficulties for the State of São Paulo. So-called "bonos rotativos" were

issued which were made valid for the payment of state taxes, and when the amount in circulation exceeded 10 billion cruzeiros, the State found that it was receiving 80 per cent of its income in bonds, which of course could not be used to pay its own employees or defray other public expenditure. The Bank of Brazil was forced to assume responsibility for most of these bonds and to make a voluminous loan to the State to enable it to meet its financial obligations. The method of making government bonds eligible to form part of the legal reserves of the banking system is really equivalent to the creation of money, unless legal reserve ratios are raised by the same proportion, in which case the measure will not stimulate the voluntary purchase of the bonds.

The dangers inherent in maintaining the liquidity of official securities and the difficulties encountered in placing them with the public have led many Governments to adopt the alternative of obliging private financial and commercial enterprises to purchase them. Such measures have taken many forms and have been employed in a number of Latin American countries. Perhaps Colombia may be considered a good example of a country which has resorted to a variety of compulsion techniques. As early as 1940, a decree required insurance companies to maintain at least 15 per cent of their capital and reserves in the form of bonds issued or guaranteed by the Republic. Later, a law was passed obliging all enterprises habitually employing more than twenty urban workers and with a minimum capital of 50,000 pesos to invest 10 per cent of their legal reserves or 2 per cent of annual profits in a bond issue, and savings banks and insurance companies also had to invest not less than 20 per cent of their deposits and 10 per cent of their reserves in such bonds. More recently, when a special tax was imposed on incomes above a certain level, it was provided that if taxpayers could show they had purchased shares in the Paz del Rio steel plant to the full extent of their new tax liability, they would be exempt from discharging it.

In Brazil, the Banco Nacional do Desenvolvimento Econômico has been capitalized almost entirely by obligatory loans from the public, which at the end of 1955 amounted to over 6 billion cruzeiros. From 1952 to 1956, taxpayers whose income exceeds a given sum have been obliged to make an additional contribution to the bank, equal to 15 per cent of their income tax liability, and firms must contribute 3 per cent of their undistributed profits. In addition, the Minister of Finance may make the following loans to the development bank compulsory: up to 4 per cent of the deposits of the federal savings banks, 25 per cent of the reserves of private insurance and investment companies, and 3 per cent of the annual receipts of the social security organizations. According to the original law, at the end of 1956 contributors will begin to receive special 5 per cent bonds to the entire extent of their loans. These bonds will be fully negotiable and will be repaid over a period of twenty years in equal annual instalments. If these repayments are financed with the real resources and earnings of the development bank, then the whole operation will not result in the direct creation of new money.

Social security reserve funds are a wealthy source of real savings in many Latin American countries, and several Governments have depended upon them to a great extent to absorb the public debt. In Argentina, since 1946,

¹² It should be mentioned, however, that the Nacional Financiera has avoided tying up substantial resources in public bonds, partly because the Banco de Mexico has been obliged to do so.

special bonds (*obligaciones de previsión social*) designed for the exclusive purchase of these entities have financed the major part of voluminous public deficits. This method is not without its limitations, however, for such reserve funds represent the real savings of contributors which must cover the future payment of social security benefits, so that their investment should be refundable over a reasonable period of time. Furthermore, in Argentina the funds have not all been devoted to capital formation but have even been used to defray a part of current expenditure. In Uruguay, where the Government has also depended principally upon the same source, social security institutions were obliged as from 1953 to restrict their purchases of official bonds in order to meet larger commitments arising from new benefits to contributors.

In spite of measures to enhance the security, liquidity and remunerativeness of official bond issues, it is frequently found that purchases by the public plus cash balances do not provide sufficient resources to cover budget deficits. Under these circumstances public authorities usually resort to credit from the central banks or similar institutions, the resources of which are not limited to the same extent as those of the private banking system because they have access directly or indirectly to new money. In some countries central banks are required to make advances to Governments in lieu of taxes receivable; in Chile such compulsory advances may amount to 12 per cent of total budgeted expenditure. At the end of each fiscal year, in Chile, these credits are consolidated into the "déficit de arrastre" or floating debt and the process begins anew. In Brazil, the Federal Government borrows from the Banco do Brasil, and when the latter requires additional funds, it discounts federal securities in its rediscount department, which in turn is empowered to request new money from the treasury for its rediscount operations. Periodically the Government's debt with the Banco do Brasil and the debt of the latter with the national treasury are cancelled, so that this type of transaction does not even form a part of the floating debt. Since March 1945, when the first of such operations was carried out, eleven cancellations have been effected—two of them in 1955—to a value exceeding 30 billion cruzeiros, or equivalent to three-fourths of the recognized federal debt at the end of 1954.

Thus deficit spending financed in this way results almost directly in the issue of new money. The method of selling to private banks bonds which can be employed as a part of legal reserves or freely rediscounted with the central bank, is equally inflationary, for instead of withdrawing from circulation means of payment which would otherwise have been spent by the private sector, it simply increases the financial capacity of the banking system. Indeed, the sale of government bonds which can be freely discounted or used as reserves permits a secondary expansion of bank credit which tends to multiply the inflationary impact of deficit financing. Furthermore, it gives the banking system a potential liquidity which impedes the application of monetary and fiscal policy.

Before the evolution of the public debt in Latin American countries is analysed, it is worth while to examine briefly some of the main causes of uncontrolled deficit spending. Aside from broader economic considerations connected with sharp fluctuations in fiscal revenue deriving from a decline in exports or other causes, or with

a sudden expansion of expenditure on account of emergencies or a contra-cyclical fiscal policy, there are technical reasons related to budget management. First, there is a tendency in Latin American countries to exclude important government operations from the budget and to authorize "créditos adicionales" to cover the deficits so incurred. In Uruguay, for example, the ordinary budget covers only about half of total expenditure, since outlays for road building and upkeep, housing projects, exchange subsidies and social security are not included, nor are public works financed with bonds or the operations of nationalized entities. This situation prevails in a considerable number of countries in the region, and is often related to another practice which reduces the flexibility of the budget.

It has become increasingly customary to earmark a certain proportion of government revenue or the receipts from particular taxes for specific uses. In Brazil, for example, over 30 per cent of the Federal Government's income and up to 50 per cent of that of some states is legally allocated in advance to given projects. Often this revenue does not even pass through the budget but forms a part of the income of some semi-autonomous agency which escapes fiscal control. This system may be a convenient way of assuring the continuity of certain projects, but it reduces the amount of resources freely available to the public authorities for adjustment to changes in budget requirements.

The third technical factor which makes budget control more difficult is the excessive decentralization of the public sector. In Ecuador, for example, not more than 40 per cent of total fiscal income accrues to the central government, autonomous institutions in this case receiving a similar or even greater proportion. An analogous situation exists in many other countries, although mostly on a smaller scale; in Brazil, however, if autonomous and semi-autonomous entities are taken into account, the federal budget includes only about a third of total public sector revenue.¹³ In such cases, there is usually a lack of co-ordination in public finance, and different entities actually find themselves competing with one another for income and credit. Failing to cover their operations with their own resources, these entities often fall back on the central government for assistance. Thus, for all these reasons, the authorities responsible for drawing up public budgets are severely handicapped in their task of trying to adjust total eventual expenditure to estimated fiscal revenue.

V. THE PUBLIC DEBT AND ITS FINANCING

Because of the difference in the nature of the internal and external public debt in most Latin American countries, the two types of debt must be analysed separately. The internal debt generally includes outstanding bonds, treasury bills and miscellaneous short-term government obligations, and, in some cases, securities guaranteed by the Government. These liabilities are in most instances the result of recorded budget operations. The external debt, on the other hand, includes credits extended to semi-autonomous agencies and public enterprises, and in some countries liabilities connected with balance-of-

¹³ It should be noted that these percentages are different from those appearing in table 1 of chapter I, owing to the inclusion here of autonomous official institutions.

payments deficits are of major importance. Thus, there is no direct connexion between budget balances and changes in the external debt. In any analysis of the inflationary implications of the public debt it is also necessary to consider the two types separately, because foreign loans, far from disturbing the relationship between means of payment and available goods and services, inject into the economy real resources equal to the amount of the loans.¹⁴

1. THE INTERNAL DEBT

As was noted in the section on public expenditure, the relative importance of debt services has tended to decline in most countries during the post-war period. It will also be seen below that the outstanding internal debt does not in general represent an exaggerated proportion of total current budgets. These facts may seem surprising in view of the large-scale deficit financing which has been practised in many countries, but they are explained by three principal contributory causes. First, in the absence of a well-developed securities market, the outstanding debt is held rather closely by official financial institutions which receive only nominal rates of interest, if indeed they are compensated at all. Secondly, in those countries where deficit spending has been most prevalent, inflation has usually been more severe, with the result that the relative value of the debt tends to diminish rapidly with the rise in prices. And thirdly, that part of budget deficits covered by the issue of new money or included in the floating debt does not usually require service payments.

Before an analysis by countries is undertaken, it is worth while to consider for a moment some of the general problems of debt management which are common to many republics. Even in countries where the change in the price level has been moderate, bond issues exist with similar repayment periods but with widely different rates of interest and provisions for tax exemption, even though the bondholders are the same. In addition, short-term debt to banks or to enterprises which execute public works escapes careful fiscal control in some countries and accounts for a disproportionate part of total service payments. The payment of extremely low interest rates, on the other hand, while appropriate for debt issues sold to official institutions, tends to discourage voluntary purchases on the part of the public.

The consolidated public debt of Argentina amounted to approximately 47 billion pesos towards the end of 1955. More than three-fourths of this sum represents bonds sold to the social security institutes, and most of the remainder is held by official financial institutions. This is not a small sum when compared with the total current budget of about 30 billion, and the official consolidated debt does not include liabilities to the banking system which amount to another 28 billion pesos. In this latter sum are included the deficit from the operations of the Instituto Argentino de Promoción del Intercambio (IAPI), principally on the purchase and sale of agricultural products; the deficit of the public transport system; and, finally, mortgage loans. This floating debt has been responsible for almost all the inflationary impact of

public sector finances, for it has not represented a transfer of the real savings of the economy such as takes place in the case of the utilization of social security contributions. In spite of the considerable expansion of the public debt in recent years, it is interesting to note that owing to inflation, current liabilities represent a smaller share of the total budget than ten years ago. However, it should be recalled that at that time an organized market for public securities existed, and mortgage operations were financed by the real savings of the community through the so-called "cédula hipotecaria".

At the end of 1954, the total floating and funded debt of the Brazilian Federal Government and local governments was estimated at 108 billion cruzeiros, which was about equal to total budgeted expenditure for 1955. This sum, however, excludes the loans obtained from the Banco do Brasil and later cancelled, and it also omits the outstanding debt of semi-autonomous agencies. The most interesting aspects of the Brazilian debt are its distribution, its recent growth, and the relatively small size of the funded as compared with the floating debt. Of the total debt, 40 billion cruzeiros corresponds to the Federal Government, 40 billion to the State of São Paulo and the remainder to the rest of the local governments. The large share incumbent on the State of São Paulo is the result of the heavy deficits which this government has incurred, and which account for most of the deficit financing recorded for Brazilian local governments during the post-war period. Half the debt of this State is composed of "restos a pagar", or payments pending for the purchase of goods and services, and "bonos rotativos", which are in the process of liquidation. The funded debt of the state amounts to only 7 billion cruzeiros. The debt of the Federal Government is distributed in a similar way. The funded debt amounts to 10 billion cruzeiros and has not changed significantly for many years; the principal items in the floating debt are the liabilities to the Banco do Brasil (which will probably be cancelled in the customary fashion), payments pending, and back contributions owed to the social security system.

The expansion of the floating debt has accounted for most of the recent growth of outstanding public liabilities in Brazil. This debt increased by 100 per cent between 1951 and 1954, while the funded debt rose by scarcely 15 per cent. A considerable proportion of the increase in the floating debt has resulted directly in issues of new currency through the Bank of Brazil, and the inflationary consequences have undoubtedly been enormous. Since 1953, a compensatory item has been the depositing with the Banco do Brasil of the earnings of the Federal Government on foreign exchange transactions, but a large part of this money has been used to finance purchases of coffee stocks and credits to agriculture. Projects for the refunding of the public debt have been under consideration in the Brazilian Congress for several years, but the immediate problem is to bring government budgets into better balance.¹⁵

The evolution of the internal public debt of Chile gives a vivid picture of the impact of hyper-inflation on public finances. The process has been a vicious circle, because since 1950 deficit financing has itself become increasingly inflationary, as the following estimates in billions of current pesos demonstrate:

¹⁴ The repayment of a large external debt can of course prove quite inflationary. In the case of Brazil, for example, current external debt servicing absorbs a considerable part of the country's capacity to import. This fact in itself significantly reduces the contribution of imports to the availability of goods and services.

¹⁵ A federal deficit of 15 billion cruzeiros is forecast for 1956.

<i>Methods of financing the deficits</i>						
	<i>Budget deficits</i>	<i>Surplus from previous fiscal years</i>	<i>Incidental receipts</i>	<i>Revaluation of foreign exchange reserves</i>	<i>Bond issues</i>	<i>Presumed increase in floating debt</i>
1950.....	2.5	1.0	0.3	—	0.9	0.3

1952.....	8.4	—	0.5	—	1.0	6.9
1953.....	13.0	—	0.6	2.8	1.0	8.6
1954.....	18.6	—	...	...	...	...

The budget deficit of 1951 was somewhat smaller than that of the previous year, but its financing was more inflationary because part of the 1950 deficit had been covered by cash balances accumulated from the 1948-49 surpluses. The deficits of the Government have increased progressively since 1951, much faster than the rise in prices, and the negative balance for 1955 was estimated privately to have amounted to about 38 billion pesos.¹⁶ Most of these deficits have been covered by increases in the floating debt which represent mainly the issue of new currency and which reached an estimated 28 billion pesos by the end of 1954. The money accruing from the devaluation of gold and foreign exchange reserves in 1953 was also completely inflationary and probably resulted in a secondary expansion of bank credit. Public bond issues are mainly held by official financial institutions, and the total amount in circulation at the end of 1954 was 19 billion pesos for the direct debt and 4 billion for that of decentralized organizations. By themselves, these obligations represented only a third of budget expenditure in 1954.

The internal national debt of Colombia has more than doubled between 1953 and 1955, reaching a figure of almost 900 million pesos as compared with a total expenditure of approximately 1,200 million in 1954. The direct cause of such an increase was the series of large budget deficits during the years in question. This change contrasts with the relative stability of the debt between 1948 and 1953. No information is available on the departmental and municipal debt, which was equal to half the national debt in 1953, but probably it too has increased significantly in recent years. If the distribution of the debt has not changed basically since 1953, when a detailed study was carried out, it is still held mainly by official institutions. Almost all national bonds have been sold by means of agreements with the Central Bank and the stabilization fund, which together held 55 per cent of the long-term debt in 1953, or by means of compulsory subscriptions on the part of commercial banks, insurance companies and savings banks, which in the same year held about 30 per cent of the long-term bonds.

In Mexico, the proportion of the internal bonded debt of the Federal Government held by official credit institutions is even larger than in Colombia. At the end of 1954, of the total debt in circulation, amounting to a little under 3 billion pesos, such institutions held over 2.3 billions, most of which sum was in the possession of the Bank of Mexico. To a certain extent this concentration of the debt in a single institution was due to the peculiar situation prevailing in 1954, when the bank was obliged not only to purchase the new flotation of 600 million pesos, but also to absorb a part of the bonds already in

circulation which were offered for sale during the liquidity crisis preceding the devaluation. The debt of the state and local governments and decentralized agencies is much more broadly distributed, more than half having been held outside public and private credit institutions at the end of 1953. In 1954 there was also a tendency on the part of the private sector—especially noticeable in the case of individuals—to disinvest in these securities, but it is likely that this trend was reversed in 1955. The largest increases in the public debt were registered in two phases during the post-war years, from 1945 to 1948 and again from 1952 to 1954. In the intermediate period, the Federal Government amortized most of its own floating debt in the Banco de México, and deficit financing by the public sector was limited mainly to short-term credits obtained by decentralized organizations. Again in 1955, even though there may not have been a contraction in the outstanding debt, the expansion was at least much smaller than during the previous year.

The internal public debt of Venezuela is insignificant, amounting to 45 million bolívares or 1.78 per cent of fiscal income in 1953. However, there exists an indirect public debt composed of government-guaranteed obligations issued by autonomous institutions and other public entities, which at the end of 1953 amounted to 260 million bolívares, or about 10 per cent of government revenue. There is also a debt consisting of short-term credits obtained by the public sector and especially by certain autonomous institutions, from private contractors and enterprises. In any event, public debt operations in Venezuela have played a very minor role in government finances, and surpluses and deficits have been related principally to changes in the treasury's cash balances.

The internal public debt of Peru is relatively more important than that of Venezuela, amounting at the end of 1955 to 1,640 million soles or about 60 per cent of government expenditure. However, this proportion has declined markedly over the last ten years, for during the period 1945-55 the debt rose by only 70 per cent while the fiscal budget increased fivefold. Most of the increase in the debt took place between 1951 and 1953, during which years it must have exerted a certain amount of inflationary pressure owing to the manner in which it was financed. Deficit financing in Peru is carried out principally by increasing the floating and short-term debt, which in recent years has been composed mainly of advances from the Central Bank on tax receipts, and is consolidated periodically into long-term obligations. This system is responsible for the fact that about two-thirds of Central Bank credit is tied up in government loans. Since 1953, however, the increase in the public debt has been more moderate.

Ecuador's public debt has also shown a tendency to expand more rapidly in recent years, although at the end of 1954 it still represented only about 25 per cent of central government revenue. The increase in the debt has mainly resulted from the substantial rise in public investment since 1950, a fact which partly accounts for the larger proportion of the outstanding debt that now corresponds to autonomous investment institutions. Also bonds issued to finance the Fondo de Regulación de Valores have contributed significantly to this rise; such bonds represented about 30 per cent of the outstanding debt at the end of 1954. The phenomenon is evidence of the great concentration of government obligations in the

¹⁶ The Minister of Finance—before the recent financial reform—predicted a deficit of 60 billion pesos for 1956.

hands of public financial institutions, which is due mainly to the undeveloped state of the securities market in Ecuador. This deficiency, it should be noted, is not attributable to monetary instability or to the lack of scrupulous servicing of the public debt, but is mainly a problem of organization.

2. THE EXTERNAL DEBT

After a long period during which Latin America's external debt remained almost stable (from the time of the defaults of the early 1930's to the end of the war), as from 1945 foreign loans to Governments and official entities again became available. The flow of foreign capital to Latin American Governments and official entities tended to increase progressively in volume during the decade 1945-55, so that, particularly in recent years and in specific countries, it has made a highly significant contribution to public sector financing. It is unfortunately very difficult to assess the increase in the region's external public debt during this period, owing to the inadequacy and lack of comparability of the information available and to the considerable scaling-down of old debt obligations. However, as a rough indication, perhaps a figure of 2.5 billion dollars is not far out of line.¹⁷ Although this capital has been very unevenly distributed in certain countries, as, for instance, Mexico, it has played a very important role in public finance.

From 1945 to 1951, almost one-third of the cumulative public deficit of Mexico was financed from abroad. (See table 37.) In spite of indemnity payments connected with

Table 37. Mexico: Financing the deficit of the public sector

the petroleum and agrarian expropriations of the 1930's, total net foreign financing was greater than the increase in the external debt, as a result of substantial donations from abroad, especially those made by the United States Government for the eradication of foot-and-mouth disease. It can also be seen from the table that during the years 1949-51, foreign funds were even more important than domestic resources in deficit financing. This remarkable fact can be explained by the origin of the deficit during the period. It arose mainly from the transactions of the decentralized organizations and state enterprises

¹⁷ This figure refers to the increase in the new short- and long-term public debt (credits minus repayments). It includes funds for general balance-of-payments purposes, since without them there would have been a greater disinvestment in monetary reserves and/or a reduction in net foreign investment (the excess of imports over exports of goods and services).

included in the public sector of Mexico.¹⁸ These entities accounted for 900 million pesos of the cumulative deficit during these years, while the Federal Government enjoyed a small surplus. It is precisely this type of official entity which has consistently received most of the new foreign capital available to the public sector, not only in Mexico but also in most other Latin American countries.

The fact that decentralized official agencies (mainly financial and development banks or corporations) and public enterprises have been the principal recipients of foreign loans extended to the public sector in Latin America, makes it difficult to carry out for other countries an analysis similar to that undertaken for Mexico, because public sector statistics in this study have been restricted to cover exclusively government operations. Thus, the transactions of semi-autonomous organizations are included only to the extent of the government transfer payments (subsidies and capital contributions) received. Changes in the external debt therefore cannot be related directly to recorded budget deficits, or even to public investment.

Nevertheless, it can be presumed that if this capital had not been available, then (a) government subsidies or capital contributions—and consequently government deficits—would have had to be much greater, or (b) the investments of these entities would have had to be reduced, or (c) it would have been necessary to replace these funds with domestic resources. Of these alternatives, however, neither (a) nor (c) would have helped to alleviate the foreign exchange problem; this is the angle that deserves the most attention, for the importance of the post-war growth of the external debt is related not so much to its contribution to global deficit financing as to the relief of the pressure on the balance of payments arising from public investments and other expenditure which absorb foreign exchange. Indeed, a very large part of the recent increase in the external public debt of Brazil and almost all of it in the case of Argentina had no direct bearing on public finances at all, but was intended to reduce the pressure of the adverse balance of payments on the general level of economic activity in these countries. Since the maintenance of employment and economic activity is a generally accepted goal of fiscal policy, this is an aspect which falls definitely within the scope of the present study.

In view of the fact that, as has been pointed out, the increase in Latin America's external public debt has been very unevenly distributed, it is necessary to analyse trends not on a global basis but country by country. Of the approximate increase of 2.5 billion dollars in the outstanding debt, about three-fifths or 1.5 billion was accounted for by Brazil alone, 0.5 billion by Argentina, something over 0.2 billion by Mexico, and the remainder—0.3 billion—by the rest of the countries of Latin America.

Most of the increment in Brazil's external debt resulted from the voluminous balance-of-payments deficits of 1951-52 and 1954. Of the total outstanding external debt

¹⁸ Ferrocarriles Nacionales de México, Petróleos Mexicanos, Comisión Federal de Electricidad, Nueva Compañía Eléctrica Chapala, Guanos y Fertilizantes, Banco Nacional Hipotecario Urbano y de Obras Públicas, Comisión México Americana para la Eradicación de la Fiebre Aftosa, etc. Not all the operations of these entities are included in the public sector, but only that part of investment expenditure not financed with their own resources or with public funds.

of 2.1 billion dollars at the end of 1955, approximately 1.2 billion can be traced directly to these balance-of-payments difficulties. Of this amount, about half is of a short-term nature, comprising principally liabilities arising from the advance sale of exchange to importers; the other half represents an originally short-term debt that has been consolidated into medium-term obligations, most of which are payable over a period of only five years. Of the long-term debt amounting to about 900 million dollars, half is accounted for by economic development credits and the other half by the old bonded debt. The importance of the role of the external debt in Brazil's balance of payments can be gauged from the fact that the post-war rise in the debt is equivalent to the total current capacity to import for one year.

As in the case of Brazil, the growth of the external debt in Argentina is of recent origin and has sprung mainly from balance-of-payments difficulties. Of the 750 million dollars estimated as the total outstanding debt at the end of 1955, 700 million constitute debts of a short-term or medium-term nature and reflect mainly deferred payments on imports and bilateral payments agreements liabilities. Although only 500 million dollars of Latin America's increased post-war indebtedness were attributed to Argentina, in reality the whole outstanding debt is of recent origin, since the country's external obligations at the end of the war—amounting to 300 million dollars—were practically all redeemed by 1947. Furthermore, in 1949, defaults on external payments caused the normal sources of commercial credit to be cut off, and since then the Central Bank has been obliged to tie up about 150 million dollars of its reserves in prepayments on imports. The recent increase in the external debt (a part of which has, of course, been involuntary) is equivalent to over one-half of Argentina's current capacity to import.

For the rest of the countries of Latin America, the increment in the external debt has not been of such importance to the over-all balance of payments, although the cases of Mexico, Colombia and Chile deserve special mention. The contribution of external financing in Mexico has already been analysed, and it was seen that the net capital inflow was sizeable, despite the considerable payments made on account of indemnities and the redemption of the old debt. The post-war net increase in Colombia's long-term public debt—most of which has been contracted during the last five years for specific development projects—approaches 100 million dollars. In addition to this capital, as from 1954 short-term balance-of-payments obligations have been incurred to supplement the capacity to import. At the end of 1955, liabilities to the United States commercial banks and the International Monetary Fund stood some 100 million dollars above the level of early 1954. The commercial arrears of Chile have also been considerable of late, and the post-war rise in the long-term external debt has been approximately equal to that registered in Colombia, but in Chile's case is of much greater significance for the balance of payments, in view of the relative stagnation of the country's capacity to import. The rest of the foreign capital received by the public sector in Latin America has been spread rather thinly, although in Ecuador it has also been relatively important.

Certain over-all trends are evident from the above analysis. During the post-war period the increase in the

external debt has in general been more closely associated than in the past with foreign exchange problems. Most of the old debt represented bonds sold to private individuals or banks in the New York and London markets to cover the cost of general public works or even to balance government budgets. Since the end of the war, most development loans have been designed to cover only the foreign exchange cost of carefully-selected specific projects; and balance-of-payments credits have been extended to consolidate short-term commercial arrears which accumulated in consequence of a shortage of foreign exchange. Most of the new credits have been received from the United States Government (principally the Export-Import Bank) and the International Bank; the relative importance of these creditors in the region's total outstanding debt rose from about 12 and 0 per cent at the end of the war to approximately 30 and 20 per cent in 1955, respectively.

(a) *The burden of external debt servicing*

The loan terms offered by Latin America's creditors differ widely. For example, the International Bank must pay between 3 and 3.5 per cent on its own long-term bonds, so that after adding its commission, it charges between 3.5 and 5 per cent on development loans. The Export-Import Bank, in pursuit of its policy of not undercutting extant market rates, charges approximately the same interest. These rates contrast with an average effective rate of only 2 per cent for Latin America's old dollar bonds. Private credits, of course, carry higher rates and, as a rule, shorter repayment terms. Perhaps a typical pattern of service charges and terms is manifest in the external debt of Colombia, where a detailed study was carried out on balances outstanding at the end of 1952. (See table 38.)

Table 38. Colombia: Financial characteristics of the external debt

(Weighted averages based on the original amount of the actual debt)

Table 38 reveals the wide range of loan terms of different lending institutions and the less favourable financial characteristics of new debt as compared with old debt. These conditions imply that by paying close attention to the problem of scheduling service charges in order to avoid the bunching of payments on short- and medium-term debt, governments can reduce the danger that balance-of-payments difficulties may arise should such payments coincide with a decline in the capacity to import. The same objective can be achieved through balanced distribution of the debt by currencies in the case of those countries which receive payment for a con-

siderable part of their exports in inconvertible moneys. Furthermore, unless a loan is expected to earn or save directly enough exchange to pay service charges, the debt burden should be related to the prospective growth of the capacity to import. These points are mentioned to emphasize the advantages of greater centralization of the power to contract external debt. Although some progress in this direction has been made recently in Latin America, in many countries official institutions or semi-

autonomous bodies can still make foreign purchases on credit without having to obtain higher authorization, and in countries where central banks or similar institutions assume responsibility for the financing of balance-of-payments deficits, more care might well be taken to avoid jeopardizing the future capacity to import. Table 39 shows the position of selected Latin American countries with respect to the projected burden of external debt servicing.

Table 39. Latin America: External debt servicing in selected countries

Country	Outstanding debt as a percentage of the capacity to import	Service charges as a percentage of the capacity to import			Service charges as a percentage of the outstanding debt at the beginning of each year

Sources: Outstanding debt and services: Information supplied by the IBRD, except for Argentina and Brazil, where data from official sources were employed. Capacity to import: Official balance-of-payments figures, the average for the years 1953-54. For Colombia and Brazil, 1953 figures were used to avoid the abnormal influence of the coffee situation in 1954.

Note: The debt to the Export-Import Bank and the IBRD includes loans both disbursed and authorized.

^a Refers to amortization payments only.

^b Medium-term and long-term debt only.

^c Excluding short-term commercial indebtedness.

The external debt of Brazil is unique of its kind for its relative size, medium- and long-term liabilities being approximately equal to the total current capacity to import. If short-term exchange liabilities are included, the debt is equal to 140 per cent of the payments capacity. Amortization payments begin in 1956 by absorbing 11 per cent of the capacity to import and will rise by 1960 to a peak of 17 per cent. A similar increase can be noted in the rate of return, which is scheduled to exceed one-third of the remaining outstanding debt by 1960. Furthermore, the currency distribution of the service charges is extremely unsatisfactory. Sterling payments scheduled for 1958 are approximately equivalent to total Brazilian exports to the United Kingdom, while in 1960 dollar payments will account for about 85 per cent of total service charges and will equal about one-third of the country's current export proceeds in convertible currencies. An added drawback is that these payments must be made at the official rate of exchange, or in other words that the Central Bank must carry a loss equal to the difference between the official rate and the average rate at which it purchases exchange (at present about 18 and 43 cruzeiros to the dollar, respectively).

The immediate service burden of Argentina's debt is twice that of Brazil, largely because most of it is composed of short-term obligations which have not been consolidated into longer-term debt. Given the country's balance-of-payments situation, the service payments schedule for 1956 create a serious problem. However, since the relation of the total debt to the capacity to

import is not disproportionate, the Government has announced its intention to re-negotiate the debt with a view to spacing out the payments more conveniently. The most serious aspect of the problem is that the country, which now requires sizeable foreign development loans, finds its capacity to absorb new debt seriously restricted by past commitments which perhaps contributed very little to capital formation.

The external debt position of Chile is quite different from that of Brazil and Argentina. Although the debt is relatively large compared with the capacity to import, scheduled service charges are relatively light. This can be explained by the fact that more than half of Chile's indebtedness is in old bonds, and that payments on the rest of the debt are well spaced out. It is interesting to note that half of the current outstanding liabilities will not be redeemed until 1965, and that between 1960 and 1970, total service charges remain at an almost constant absolute level of some 15 million dollars a year. In spite of the satisfactory timing of debt repayments, however, Chile's capacity to absorb new loans will be limited, unless the capacity to import grows more intensively.

Although in other countries of the region the relation of outstanding debt to the capacity to import varies considerably, the burden of service charges displays a rather similar pattern. In both Colombia and Nicaragua, however, the burden seems to be somewhat heavier than is justified by the size of the debt. This discrepancy is explained by the bunching of service charges on short-term and medium-term obligations in the near future. In Co-

lombia, a third of the external debt comes up for redemption during the three years 1956-58; in Nicaragua, over two-thirds of the debt must be liquidated during this period, owing to the unusual magnitude of privately-placed medium-term liabilities, which at the end of 1954 accounted for almost 40 per cent of the country's outstanding external debt. In Ecuador and Paraguay, a similar situation is responsible for the relatively heavy payments scheduled for 1958.

In general, it can be concluded that most Latin American countries are in a position to finance a larger external public debt. It is clear from table 39, however, that if lending institutions and loan terms are not selected with care to avoid a very uneven spacing of service charges, an unplanned debt expansion may lead not only to balance-of-payments difficulties but perhaps to defaults, which might endanger the defaulting country's chances of obtaining future foreign loans.

Chapter IV

EXCHANGE POLICY AS A FISCAL INSTRUMENT

I. FISCAL ASPECTS OF EXCHANGE POLICY

In principle, exchange policy does not envisage objectives of a fiscal character and in any case such aims are rarely stated officially. Nevertheless, there have been major repercussions of this kind since the adoption of exchange controls and it is clear that fiscal considerations have not only contributed to the permanency of controls but have also inspired the reform of such systems.

An early feature of the official control of exchange markets and of the establishment of multiple exchange rates was that the State gained a source of revenue which, without falling specifically into any of the traditional categories, clearly had the character of a tax.

The purchase and sale of foreign exchange at differential rates, the profits derived from these operations and the expenditure of such revenue by the State, are all in the nature of a transfer of income from one sector to another. But, despite the apparent simplicity of the mechanism, it is not always easy to establish which sectors have suffered and which have obtained an advantage, or the size of the burden or benefit. The purchase by the State of the foreign exchange earned by the exporter will represent either a surcharge or a subsidy on export activities, according to the purchase price. The same is true for imports. If the sales price for foreign exchange is high, this in principle constitutes a tax on imports or on the consumption of the goods concerned; a low price would imply a subsidy for consumption.

Since it is the fiscal aspect of exchange policy that is being discussed here, the analysis must be made in terms of the actual income obtained by the State from the exchange system, of the use of this revenue and of the surcharge or subsidy affecting the different categories of imports or exports, with due regard to their relative position as regards the differential treatment they receive in the purchase and sale of foreign currencies. Other considerations are discussed only in the case of Chile and with the aim of posing a problem worthy of more detailed research.

Exchange policy is also linked with public finance when differential exchange rates, in so far as they are a concealed form of taxation, replace regular taxes. An obvious example is that of the exchange surcharge applied to imports for purposes of protection and which either operates in conjunction with customs duties or is substituted for them. This device of economic policy may originate in a tariff which is too low or whose institutional rigidity is due to trade agreements or legislation which cannot easily be modified; again, it may arise from the greater adaptability of an exchange surcharge to changing circumstances or simply from practical motives connected with the system of tax collection.

Another interesting case is that of taxation which results directly from modifications of the exchange rate or

from certain effects of the rate already in force. For example, at times monetary devaluation has been accompanied by the taxation of exports, in order to obtain as revenue some of the benefits which would otherwise be transmitted exclusively to the export sector; on other occasions, a similar tax for the same purpose has been applied when the profits are due to higher world prices and to prevailing exchange rates which were pegged when market conditions were different.

From a broader standpoint, exchange policy is linked with public finance by the varied repercussions of the former upon internal economic activity, the possible harmful effects of which must at times be offset by a well-balanced fiscal policy. For instance, austerity and financial discipline are usually indispensable when the inflationary effects of a devaluation of exchange rates are to be offset or reduced.

Although the Latin American economies have common features, differences exist which occasion the adoption of diverse exchange policies. The last ten years have been rich in such examples.

The instruments employed are those already familiar, namely, exchange rates which begin as differential rates for purchase and for sale and then split into still others for the individual categories of exports and imports. Each country or group of countries applies different treatment to the same or similar categories. A variety of criteria determine these distinctions, but almost all of them are related to the nature of basic exports and the proportion of aggregate exports they represent, to the relative productivity of export activities and their contribution to national income, and to the characteristics of the world market where they are sold. These criteria are obviously related to the balance-of-payments situation, to the existence or absence of inflation and to the general direction of economic policy. Even so, the objectives are similar in almost every case; maintenance of equilibrium in the balance of payments; selective restriction of imports; higher exports; development of secondary exports; increased investment; and preservation of consumption levels.

II. ANALYSIS BY COUNTRIES

Despite the common objectives noted above, and even where two or more countries can be united in a single group because of the similar nature of their exports, the problems involved are not always identical and as a result both exchange policy and fiscal effects differ. It is thus pertinent to make a special analysis of these problems in four countries where the exchange systems may be considered as representative, before briefly outlining the main features in the other countries as a whole.

1. CHILE

Chile's exchange system is one of the most complex and has the most important fiscal repercussions. Since long before 1945, it has been characterized by the existence of multiple and overvaluated rates, as well as by the application of more or less broad controls on imports and exports. But the outstanding feature of the system is the role played by the taxation of the large copper mining companies.¹

Copper exports carry almost the entire weight of the monetary overvaluation. On the import side, the benefits of overvaluation have been concentrated, in the form of subsidies, on a few commodities which were the most essential or had most effect upon the cost of living.

This transfer of income is based on the very special characteristics of the copper industry in Chile. Productivity is much higher than that of other sectors and mining is carried out by three large foreign companies, which employ less than one per cent of the active population but produce about 8 per cent of Chile's gross income. This is why tax proceeds accruing from copper constitute a large share of fiscal revenue and why the proportion of copper income falling to Chile has grown from 30 per cent in 1929 to 70-80 per cent in recent years. The exchange subsidies established in 1932 have come to represent one of the major items in transfers and in public expenditure, as may be seen in chapter II.

The taxes levied on large mining companies may be classified in four categories: income tax; customs duties; taxes on sales or surtax; and the so-called implicit tax on production costs. The first three categories are collected in dollars which the Government converts into Chilean pesos at a specific rate of exchange; for many years this was pegged at 31 pesos to the dollar and represented the official par value. After devaluation in 1953, the rate became 110 pesos to the dollar.

The implicit tax on production costs represents the difference between the exchange rate at which the Government purchases the dollars which the copper companies must sell to cover expenses payable in Chilean currency, and the rate at which the Government sells the dollars. Between 1935 and 1951, the purchase rate stood at 19.37 pesos to the dollar; as from the latter year, it was applied to only part of the purchases, and exchange rates of 50 pesos to the dollar in 1952, 60 in the following year and 110 in 1954 were applied to the remaining part. Hence the average rates for each of these years were 23, 34 and 62 pesos, respectively. By the Act of 1955, which modified the statute relating to copper, this "returned-value" rate of exchange was established at the average rate applied to the majority of Chilean exports and became 200 pesos to the dollar until November 1955, when it rose to 300 pesos.

Various rates of exchange have been in force for other exports during the last ten years. Thus a small proportion of nitrate shipments was allotted a rate of 19.37 pesos to the dollar and the remainder had a more favourable rate; agricultural exports, wine, fish and the products of the

small mining companies, on the other hand, enjoyed preferential rates. At the end of 1955, the prevailing rate for most exports stood at 300 pesos to the dollar and the free market rate was applied to fish, wines and some of the iron ore produced by the small and medium mining companies.

The selling rates for foreign exchange have frequently altered during recent years. Between 1948 and 1950, the rates varied from 19.47 pesos to the dollar for some government transactions to 43.10 for the majority of imports. Essential imports benefited from a rate between 25.10 and 31.10. Successive devaluations of the peso have raised the rate to 110 for imports of sugar, kerosene and antibiotics, to 200 for government imports, official payments and some private purchases, and to 300 for all other imports, except luxury goods which can only be bought at the free exchange rate.

As under any similar *modus operandi*, the fiscal profits on exchange controls accrue from the difference between the average purchase rate of the exchange and the average sales rate. But in the case of Chile—perhaps as in no other country in Latin America—difficulties arise from two circumstances which were mentioned previously: the nature of copper taxation and the monetary overvaluation.

From the fiscal standpoint, Government revenue in dollars comes from two very different sources, namely, from taxation, and from official exchange purchases from the copper companies and the other export sectors. For both, accounting is done in Chilean pesos, for the former at the agreed or official exchange rates already mentioned and for the latter at the actual purchase price. A comparison of the total, in pesos, of this revenue with the sum, also in pesos, derived from the sale of foreign currencies, gives the exchange differential accruing to the Government. (See table 40.)

The first remark to be made on this procedure arises from the method of accounting used for the dollars obtained from the copper companies in the form of taxation. Since these are not dollars purchased by the Government, it is clear that the rate of exchange applied purely for accounting purposes—and even corresponding to the official par rate—is conventional or arbitrary, since it does not represent the real value of the exchange received. If a different method of evaluation were adopted for accounting purposes, the difference would be smaller and might even be converted into a loss. The same is not true of the other exchange operations, including purchases from the copper companies of dollars at the "returned-value" rate, because, in this case, the "cost" of the dollars is expressed by the purchase price.

The sale price—or the price at which the Government sells its foreign exchange—represents the other side of official exchange operations. This price, even allowing for the heavy subsidy on some imports or on official payments, is on the average higher than the purchase price or than the accounting rate at which it appears as fiscal revenue; but, whatever the net result, it is lower than that corresponding to the real par value based on a comparison of the respective purchasing power of the peso and the dollar. In other words, there is apparently a new exchange differential, that existing between the sale price and the real par value. This is obviously not

¹ The fiscal aspects of the exchange system in Chile and their connexion with copper mining have received more detailed analysis in a recent ECLA study. See "3. Some aspects of the inflationary process in Chile", *Economic Bulletin for Latin America*, Vol. I, No. 1, January 1956, pp. 43 et seq.

^a Explicit exchange differentials are the differentials between the selling rates and the effective or accounting buying rate of exchange. Implicit exchange differentials are the differentials between the selling rates and the calculated purchasing power parity rate of exchange.

effective income which provides a share of fiscal resources, but will in any event represent what the State fails to gain because it sells the exchange at a price lower than the par value. Even so, two further reservations must be made: firstly, that arising from the similarly artificial character of the purchase or accounting price; secondly, that deriving from the relative nature of the par value, which is also affected by the exchange system in so far as the latter influences the level of domestic prices.

If, despite its drawbacks, this procedure for calculation is adopted, it may be seen that the "theoretical" profit, or the exchange differential which did not reach the budget, would have represented more than 20 per cent of fiscal revenue during the last few years. (See again table 40.)

It is useful, when attempting to assess the subsidy for imports, to compare the sale price of foreign exchange and the rate of the real par value. The relationship between them will represent the size of the subsidy. Thus, the subsidy for imports during 1950-53 represented on an average 47.1 per cent of the price in the case of consumer goods, 38.1 per cent in that of raw materials, 41.1 per cent in that of fuels and 24.3 per cent in that of capital goods.²

These characteristics of the exchange system in Chile are having broad repercussions upon the whole economy, which have already been analysed elsewhere.³ At the fiscal level, they take the form of effective budgetary income, which is mostly derived from the copper-mining industry. In addition, the monetary overvaluation causes a transfer of income from copper—and to a small extent

from the nitrate industry—to the community in the form of subsidies on consumption.

This policy of subsidies is to a large extent responsible for the crisis through which the system is passing. The share of the copper industry's high productivity transferred to the national economy has been used for consumption rather than investment; and the maintenance of subsidies, when copper exports declined sharply, has been one of the major reasons for the enormous fiscal deficit in Chile and for the accelerated pace of inflation during recent years.⁴

2. VENEZUELA

Venezuela has some features in common with Chile as a result of the influence of the petroleum industry on the national economy. Like copper in Chile, petroleum in Venezuela is the basic export activity, its exploitation is also in the hands of foreign companies, taxation on petroleum is the main source of fiscal revenue, and the

⁴ The recovery of these exports, as a result of higher world prices for copper, coincided with a radical change in the exchange system which was authorized in April 1956. The reorganization establishes a free rate of exchange, which fluctuates according to supply and demand, and will apply to all imports and exports. The system of import licences is abolished, but only those imports are permitted which appear in a previously prepared list. An annual list of prohibited agricultural exports will also be in force. A prior deposit of a percentage of individual purchases abroad must be made with the Banco Central by every importer, the percentage depending upon a classified schedule; this deposit may exceed 100 per cent. In practice, the exchange differentials thus disappear, especially since the exchange accruing from copper exports is included in the new system, except during 1956 when they will be bought at a rate lower than the anticipated free market rate and up to a value of 30 million dollars. A few imports—sugar, tea, yerba mate, kerosene and antibiotics—will continue to enjoy an exchange subsidy through the reimbursement which the Government will make to importers of the difference between the rate of 300 pesos to the dollar and that which the importer must pay on the free market. In addition to the "banking exchange market", a further money market is also permitted where foreign currencies earned from the tourist trade can be negotiated, as well as exchange deriving from capital transfers, profits, dividends and interest which are not specifically channelled through the banking exchange market.

² Another criterion might be to compare the exchange rate applied to specific imports with the average rate used for all imports. Nevertheless, this procedure would lead to artificial results in the case of Chile, given the high proportion of subsidized imports.

³ The study mentioned in footnote 1 to this chapter represents a first analysis in which the concept of the real par value is applied and where references will be found to the methodology used here. See also "III. Inflation and anti-inflationary policy. A. The example of Chile", in the *Economic Survey of Latin America*, 1954, *op. cit.* pp. 22-38.

product generated by petroleum represents 31 per cent of the gross national product, although it uses a very small share of internal productive resources.

These similarities are accompanied by marked contrasts. Dependence upon a single export is far greater in Venezuela; petroleum represents 94 per cent of all exports and the demand and price are more stable than those of Chilean copper, which has been subject to violent fluctuations causing sharp economic disequilibria. Venezuela has no inflation and the level of domestic prices has remained remarkably constant in recent years.

It is on account of these factors that, despite certain common features, Venezuela's exchange policy differs greatly from that of Chile as regards both methods and objectives. In the strict sense, there is no exchange control in Venezuela, except that the petroleum companies are obliged to sell their foreign exchange to the Central Bank at a fixed rate in so far as they require funds to cover their local currency expenditure. Moreover, foreign trade is subject only to restrictions on the import of a few article for protection purposes, the prohibition of exports of strategic materials to certain countries and licences for the export of some commodities considered as essential to the national economy.

The exchange system is thus relatively simple. The petroleum companies must sell foreign exchange to the Central Bank at the rate of 3.09 bolivars per dollar and, if the amount of this exchange exceeds sales made by the Bank during the year, the rate of 3.046 is applied to the difference. A rate of 3.33 bolivars is in force for other exports, except coffee and cacao, which enjoy preferential rates of 4.80 and 4.25 respectively if their world prices fall below a given level; these rates have not been applied in recent years, however. The selling rate is 3.09 bolivars for official payments and 3.35 for all others.

In all its essential aspects, this system has been in force since 1941. Until that date, the disadvantage of the high exchange rate resulting from petroleum exports had been offset for agriculture by direct subsidies, but the latter were abolished when the new system was introduced in 1941.

The exchange differential between the buying and selling rates provides the State with a source of revenue which has, in recent years, amounted to slightly more than 5 per cent of aggregate fiscal resources. (See table 41.)

This income has enabled the State to subsidize coffee and cacao exports and, in particular, to increase ordinary revenue. This, then, is one of the simplest examples of an exchange policy that provides the State with comparatively modest resources which, nevertheless, are by no means insignificant in absolute terms.

3. BRAZIL

Brazil's exchange policy differs substantially from that of the countries already examined. The outstanding feature common to all of them lies in the pronounced concentration of exports in a few products, and in one commodity in particular. But, in the case of Brazil, coffee is an agricultural product and is subject not only to violent price fluctuations on consumer markets, but also

to the hazards of weather conditions. Moreover, coffee-growing employs a high proportion of national productive resources and has nothing like so high a productivity as the Chilean copper industry or the petroleum industry in Venezuela.

Exchange policy is closely linked to the situation of coffee and is adapted to its vicissitudes. As a rule, revenue is drawn from the coffee sector for the benefit of other activities or of the State itself, but recently, such taxation has been reduced as the coffee market has weakened. In the first instance, the basic export sector has transferred income to other sectors, particularly to consumers and importers and, more recently, to secondary exports. In the second, particularly since 1953, basic exports have been subsidized by exchange bonuses accruing from taxes imposed on importers or on the community as a whole.

The multiple exchange system which had been in force until 1946 was simplified in that year and two rates only were established. Between 1948 and the beginning of 1953 the basic purchase rate stood at 18.38 cruzeiros per dollar while the basic selling rate was 18.72 cruzeiros. For some non-essential imports, certain invisible items and some remittances, a rate of 3 per cent above the basic selling rate was applied; this rose to 8 per cent in January 1952. The restriction of imports during this period was effected through import licences. Despite an increase of 100 per cent in domestic prices during the period 1945-52, those exchange rates were maintained thanks to the rise of approximately 135 per cent in coffee prices. This improvement in the price of coffee, and the somewhat smaller increase in domestic prices, affected both other exports and imports. Secondary exports, entitled "gravosas", were discouraged, since they were obliged to bear the dual burden of a rise in their domestic production costs and of an exchange rate which was excessively overvalued.

Conversely, imports were encouraged by the overvaluation and by the abundant means of payment when controls were slackened with the deliberate aim of increasing supplies from abroad. The low exchange rate did not in many cases prevent a rise in the price of imported commodities on the domestic market and the importer, rather than the consumer, thus reaped the benefits of overvaluation.

It has often been said that during this period the rise in coffee prices obscured or camouflaged the overvalua-

tion of the cruzeiro, which, in point of fact, did not weaken coffee exports, because the world market price was sufficiently high to provide the coffee sector with adequate profits.⁵ They would have been even greater if a more realistic exchange rate had been available. It may be said that the share of the profit which was lost through overvaluation was transferred to other sectors. Secondary exports, prices for which were not sufficiently high to offset the rise in domestic production costs, suffered effective losses which also favoured the other sectors.

This is the type of transfer which the exchange system caused up to 1952. The difference between the buying and selling rate was too small to produce any obvious repercussions in the fiscal sphere.

The halt in the upswing of coffee prices during 1950-52 and the situation of the secondary exports led to the exchange reforms of 1953. The first of these, introduced in February, created two markets. There was one of an official character, where the quotations previously fixed were maintained and which was available to basic exports, a proportion of secondary exports and essential imports. The other was a free market, where quotations were regulated by supply and demand, and to which the remaining proceeds of secondary exports and less essential imports had access. During the short period when this system was in force some changes were made, which almost all tended to an extension of the free market in favour of other exports, including coffee and cacao to some extent.

The second reform, adopted in October 1953, was more radical and is still in force. The most important innovation was the creation of an auction market, which rationed the available exchange among imports, according to their nature as essential or non-essential, through the establishment of an exchange quota for each of the five categories and a basic rate for bids. Under this system certificates are sold which entitle the holder to buy foreign exchange at the official rate. Hence the real sales rate is the sum of the official rate of exchange, the purchase price of the certificate and the transfer tax. Exports, in turn, are negotiated at the official exchange rate, plus a bonus or subsidy.

Several changes have been introduced into this system, comprising the transfer of imported goods from one category to another, alterations in the subsidies granted and, finally, the introduction of categories for exports as well.

The substantial difference between the auction market selling rates and the purchase rates fixed for exports has produced a large volume of State Revenue. (See table 42.)

The size of these resources becomes evident when they are compared with those obtained, for instance, from customs duties and with aggregate fiscal revenue. From the time the system was introduced until December 1955, revenue from exchange differentials amounted to 74,316 million cruzeiros and export subsidies to 47,614 millions. This was possible because, while the exchange rate for coffee rose from 23.36 cruzeiros to the dollar in October 1953 to 37.06 in September 1955, and the rate for other

^c Approximation, based on budget estimates.

exports from 28.36 to 50.06 cruzeiros, the average auction market rates increased from 40.91 to 78.88 cruzeiros during the same period.

The most favoured imports and payments include newsprint, petroleum, coal and essential machinery, some government imports—including wheat—and some official and private remittances. All of these are negotiated at the official exchange rate (18.82 to the dollar), plus a varying surcharge. Other imports are assigned to one of the five established categories, according to how far they are essential for the country's economic development and its supply needs; they are dealt with on the auction market under differing conditions.

Exports, in turn, are classified in four categories, with effective exchange rates of 31.50, 37.06, 43.06 and 50.06 cruzeiros to the dollar, respectively. Coffee was originally included in the first category, but was soon transferred to the second, in which cacao and cotton, among other products, are also included.

According to the latest modifications in the system, the Government will employ the exchange proceeds for the following purposes in the order given: (a) payment of bonuses to exporters; (b) regularization of the exchange operations carried out for the Treasury before the law came into force; (c) long-term financing at low interest rates of the modernization of methods of agricultural production, purchases of products, seed, fertilizers, machinery, etc.⁶

Briefly, then, before the 1953 reform, the high price of coffee enabled consumption to be subsidized through the low exchange rate granted to imports and, in some cases, to secondary exports. The small bonus of 5 cruzeiros per dollar granted to coffee during the first year that the new exchange law was in force had little effect on the transfer mechanism.⁷ But the situation changed in 1954, when the deterioration of world prices made it essential that coffee and other products should be subsidized, at least in regard to the official par value of the cruzeiro. Government and essential imports continued for some time to enjoy the benefits of the exchange subsidy, which had practically disappeared by 1955. Hence, the whole incidence of exchange taxation fell on the less favoured imports, that is to say, upon the consumer. The

⁵ See *Economic Survey of Latin America, 1953* (E/CN.12/358), United Nations publication, Sales No.: 1954.II.G.1, pp. 127 *et seq.* An indication is given there of the reservations to which these estimates should be subject.

⁶ From the time when the system was introduced until the end of 1954, 6,370 million cruzeiros were used to buy coffee surpluses and 2,694 millions for other agricultural loans. (See Banco do Brasil, *Relatório de 1954*, p. 60.)

⁷ Except for imports in the high categories, which ceased to be subsidized.

gradual removal of subsidies has aggravated the burden of this taxation.

Brazil provides a typical example of the replacement of customs duties by exchange taxation, both from the point of view of protection and from that of fiscal revenue. This is evident not only from a comparison of the yields of the different sources of revenue, but also from the fact that customs tariffs have remained unmodified for many years.

4. ARGENTINA

Argentina's exports are far more diversified than those of the other three countries examined in this chapter. But the relatively varied commodities which comprise the majority of its sales abroad are all agricultural products. Hence diversification does not prevent the fluctuations resulting from weather conditions which frequently affect the major sectors, nor those arising from changes in world demand and prices, which are often common to nearly all these commodities. External factors, and others deriving from economic policy or industrialization, have brought about a gradual but persistent decline in agricultural activity. This is reflected in the reduction of the area sown, a phenomenon which has been analysed in earlier studies.⁸

The vicissitudes of the crop and livestock sector, which constitutes the basis not only of the capacity to import but also of the whole of Argentina's economy, have determined the main features of its exchange system and vice versa. At times, the system was aimed at protecting rural activities through the granting of preferential exchange rates, at others, the objective was to tax excess profits for the benefit of other sectors of the community. Market instability also led in 1946 to the creation of the Instituto Argentino para la Promoción del Intercambio (IAPI), whose work from that date was closely linked to exchange policy.

Exchange controls and fiscal profits derived from differential rates already have a tradition in Argentina. Until 1939, the prevailing system gave preferential treatment to secondary exports or those shipped to neighbouring countries and permitted exporters to dispose freely of their earnings. Imports were subject to licensing, priorities being given to essential goods or government imports. Multiple exchange rates were established in 1935, while in 1941 the auction or bidding system was introduced. This policy remained practically unchanged until October 1949, when imports were divided into five categories, the last of which was negotiated on the exchange auction market; the rates varied from 3.73 pesos per dollar to 12.53, the most favourable rate being that applied to fuels. Exchange rates for exports ranged from 3.35 to 8.98 pesos, the lowest being assigned to regular or basic exports.

The system was simplified in August 1950, when the number of basic rates was reduced to two—5.00 and 7.50 pesos per dollar—plus a so-called free rate, which was nevertheless officially controlled and which fluctuated around 14 pesos per dollar. The principle of assigning the lowest rates to basic exports⁹ and to the more essen-

tial imports, and of fixing the highest rates for secondary and luxury imports, remained the same. The simplification was only on the surface, since various combinations of the exchange rates were made, by applying them to percentages of the different goods; a multiplicity of rates thus appeared, even though regular imports continued to be negotiated at 5 pesos to the dollar. This was the prevailing system until it was abolished in 1955. The margin of exchange proceeds reached high figures in some years, when it exceeded revenue from other traditional tax sources.

The drop in world prices and other circumstances unfavourable to the basic export trade caused this margin almost to disappear in 1953-54. (See table 43.)

Table 43. Argentina: Tax income, exchange margin, internal taxes and property taxation

Source: Official data.

It is difficult to understand the working of the system without a reference to the minimum prices fixed by the Government for the purchase of certain products. These prices were established by IAPI on the basis of world prices and the overvalued exchange rates; they thus affected the position of the agricultural sector. In favourable years, the exchange rate led to the establishment of prices which annulled a large proportion of the farmers' profits. In unfavourable years, the new prices gave only slight relief, which in many cases was merely transitory. World prices directly affected IAPI, a marketing organization which at first made good profits, but later experienced losses that had to be financed by inflationary methods. Such losses were recorded in several years, but were particularly heavy in 1953 and 1954. (See table 44.)

These losses display a peculiar feature. They were incurred by an official institution which resorted to credit

⁸ Apart from recent *Economic Surveys*, see "The situation in Argentina and the new economic policy", *Economic Bulletin of Latin America*, op. cit., pp. 26 et seq.

⁹ There were exceptions, wool, for example.

from public banking institutions; these, in their turn, obtained credit from the Central Bank, another official organ. The inflationary pressure provoked by the creation of this additional money supply meant that it was in fact

the community that was ultimately obliged to bear the losses through inflation, while no effective benefits accrued to the farmer. The same is true of the subsidies which IAPI granted to various activities. (See table 45.)

^c Exports of dairy products.

Two remarks are pertinent here. First, the advantages of an apparently remunerative price or of a subsidy were to a large extent neutralized by the higher exchange rates at which the very sectors benefiting from such measures were obliged to negotiate their purchases of imports. Second, IAPI's profit or loss was derived not only from the exchange rate but also from the ratio between the purchase and sale prices of the products concerned.

The monetary overvaluation had a more direct effect on producers of export goods for which there were no minimum official prices.¹⁰

This very brief review of Argentina's exchange system allows some conclusions to be drawn as to its fiscal aspects. In the first place, profits from exchange differentials were incorporated into the ordinary revenue of the State without being earmarked for any specific purpose. Moreover, the profits obtained by IAPI, an official agency, were derived not only from currency overvaluation, but also from negotiations carried out by this institute, including imports. Because the situation changed as a result of world prices and demand, the profit disappeared and the marketing of the harvests led to heavy losses for IAPI. The overvalued exchange rate for basic exports allowed more advantageous rates to be accorded to minor exports, even if such rates were lower than those of the real par value. Currency overvaluation favoured imports, but only in a few cases was the benefit converted into an advantage for the consumer, since the profit very frequently remained in the hands of middlemen and the whole system contributed to accelerated inflation and a higher cost of living.

In favourable years, therefore, the agricultural sector was burdened with exchange taxation for the benefit of the State, of other exporting sectors, of middlemen dealing with imports and, in only a few cases—such as fuels and newsprint, for example—of the consumer. The situation in recent years, when world prices have been low, has strengthened the role of exchange policy in taxation.

On the other hand, overvaluation has created a subsidy for imports of fuels and capital goods, which have ab-

sorbed a greatly increased share of aggregate imports during the last ten years.¹¹

The exchange reform of 28 October 1955 sanctioned a sharp devaluation of the national currency, by raising the official rate to 18 pesos per dollar, and established a free market. The first of these measures was applicable to basic and other less important exports, as well as to essential imports; and the second to all other exports and imports.¹²

The official rate was thus placed on a more realistic level and, if it represents the dollar purchasing power of the peso, will abolish the taxation through the exchange rate which was formerly borne by exports. But another burden has appeared, which is more specifically in the nature of taxation; the Government has established a "retention" on the official rate, which varies from 10 to 25 per cent. There are thus five effective rates, the lowest "retention" affecting exports of grain, oilseeds and other less important products. Mining products, tanned hides and some fibres enjoy the full benefit of the official rate.

There are similar surcharges on certain imports, which in some cases, such as that of passenger cars, are extremely high.

Retentions from exporters and importers form the Economic Rehabilitation Fund, which is used to finance technological and economic improvements in agriculture and to pay whatever subsidies may have to be granted in order to mitigate the possible effects of the devaluation upon production costs.

It is clear that the fiscal repercussions of exchange policy are intensified by this latter part of the new system. The retentions and surcharges mentioned here in fact represent taxation. In some cases they affect the excess profits which may, at least over the short term, arise through currency devaluation, while in others they weigh

¹¹ Since the percentages of imports of these goods relate to a decreasing volume of aggregate imports, their contribution to industrialization has been slight. (See also the article mentioned in footnote 8.)

¹² For other aspects and details of the exchange reform in Argentina, see the article mentioned in footnote 8.

¹⁰ In some cases compensation was provided in the form of direct subsidies.

upon the consumption of imported non-essential or luxury goods.

The funds obtained by these means are set aside for purposes closely linked to the promotion of economic development. Exchange facilities granted for the entry of foreign capital, in either physical or monetary form, are for a similar purpose. Foreign exchange from this source can be negotiated on the free market. Moreover, all obstacles to the remitting of profits or the repatriation of capital have been removed in the case of funds invested since 30 June 1955.

5. OTHER COUNTRIES

Except for those few instances where no exchange controls are in force—Peru, for instance—exchange systems in the other countries of the region share some features of those prevailing in the four countries just dealt with, which, as noted, are the most typical or representative.

The establishment of an exchange margin fund is common to the majority of the countries. In most cases, the fund is supplied from the differentials between multiple rates; in others, like that of Cuba, its resources accrue from taxes on certain foreign currency transactions. In some of the countries—Cuba, Nicaragua and Paraguay, for example—exchange resources enter the budget without being earmarked for any special purpose, although a share is devoted to the amortization of loans in Cuba and to public works in Nicaragua. In Colombia, 30 per cent of the so-called “coffee differential”—which was eliminated in 1955—entered the budget, while the remainder was transferred to the Federación de Cafeteros for investment in agricultural development.

As a consequence of the successive currency devaluations in 1948, 1949 and 1954, Mexico introduced taxes on exports aimed at mitigating the inflationary effects of devaluation and reducing the profits arising from it. From the fiscal angle, the tax in this case had the same effect as multiple exchange rates.

The revenue obtained by Ecuador from the exchange control system has been applied to a number of development objectives and also to subsidies. Between 1944 and 1953 funds entering the budget amounted to only 32 per cent of the full value collected under this item.

The revenue derived from the exchange margin in these other countries is by no means insignificant. Thus,

in Cuba it amounted to 4 per cent of aggregate budget revenue in 1953-54, and, given the variety of taxes, revenue from exchange differentials compares favourably with that accruing from many of the other sources. In Nicaragua, exchange surcharges and differentials yielded larger proceeds than income tax in 1954-55. The export tax adopted in Mexico provided 939.1 million pesos in 1954 and was of great help in covering fiscal requirements swollen by devaluation. It is estimated that in Ecuador the receipts from taxes on import permits amounted to over 360 million sucres between December 1950 and the same month in 1953.

Methods used for control and for taxation are not always identical. But, as in the countries previously considered, exchange policy is carried out in these other cases through multiple rates and through export or import taxes in the form of exchange surcharges. In any event, these are all explicit or concealed ways of establishing exchange rate differentials and their adoption depends upon the ends in view. The classification of imports by categories, according to the extent to which they are essential, and the application of varying exchange rates are perhaps the most common features.

Differential treatment of exports, as a means to their diversification, has also appeared in all of these countries; trade policy has thus been obliged to take the position of the basic groups very carefully into account, and to adapt itself to fluctuations in world prices and markets. In this sense, the exchange problems of Colombia, for instance, are very similar to those of Brazil, since both countries export coffee. In 1951, Colombian coffee exports were negotiated at exchange rates lower than the official par value, but the reform in 1955 removed this burden, which had been modified on several occasions in the interim. Exchange policy in Colombia has also been combined with taxes on exports of the country's basic commodity, as in the case of Brazil, or with the fixing of minimum prices, as in Argentina.

Events in Colombia emphasize the fact that the exchange system has also been enlisted in the service of an import replacement policy, the most recent step in this direction being the stamp tax, which acts as an exchange surcharge that varies according to the category of the imports concerned.¹³

¹³ For a full discussion of Colombia's exchange policy, see chapter V of *The Economic Development of Colombia* (E/CN.12/365), to be published in the near future.
