ECONOMIES OF SCALE IN THE COTTON SPINNING AND WEAVING INDUSTRY

I. INTRODUCTION AND CONCLUSIONS

1. Introduction

The experience gathered in the field of the textile industry seemed to suggest that both in investment and in production costs the economies resulting from an increase in the scale of production are minimal. The fact that not only in Latin America but also in other more highly industrialized regions there are a great many small mills - some of them with fewer than 5,000 spindles - capable of competing in the market with large establishments would seem, at first glance, to constitute the most striking evidence in support of this statement. Furthermore, an analysis of the structure of production costs in an integrated spinning and weaving mill shows that the variable cost components represent between 60 and 80 per cent of total costs, according to the nature of the goods produced. The reduction in fixed costs, which are those most affected by production scales, would therefore have to be very great for economies of scale to be achieved in the textile industry. A preliminary survey carried out by ECLA[1/] in relation to three different products showed negligible variations in unit production costs, amounting to 9 per cent in the at most 9 cases studied. But in view of the limitations of this preliminary research, especially with regard to the scales of production envisaged, ECLA decided to undertake a more thorough investigation which would virtually cover all sizes of mills existing in Latin America, from the largest to the smallest.

Accordingly, the primary objective of the present study is to determine the savings in investment and production costs obtainable by increasing mill sizes in the cotton textile industry. Nevertheless, it provides general information on investment, costs, employment of manpower, production techniques and many other aspects of the question, which, if properly analysed, will make it possible to establish coefficients that

---

1/ See Economías de escala en la industria textil (ST/ECLA/Conf.11/L.20).

/will be

will be of use to those concerned in solving the problems of the textile industry, either at the level of the enterprise itself or in the macro-economic field.

In the preparation of this study, special attention was devoted to the methodology applied, and on several occasions the calculations were based on an amount of detail that might seem excessive. This care was necessary, however, because, as already pointed out, previous experience had indicated that economies of scale were of little importance in the textile sector. Less meticulous estimates would have affected the results obtained and distorted the conclusions formulated.

The precision with which the production units in the 24 examples studied were described, especially as regards output data and investment requirements, will also place at the disposal of textile entrepreneurs and project engineers information that will be of particular value in the selection of products and mill sizes. They will be able to obtain such information either by using coefficients derived from the study or by introducing appropriate modifications in any of the cases considered. It is worth while pointing out that, where a specific project is concerned, the data contained in the present study will need further processing and will have to be supplemented and adjusted to local conditions.

The concept of economy of scale adopted in this study is the variation in investment and production costs per unit of output which takes place in a given project, as the capacity of the mill is expanded, always on the assumption that installed capacity is being utilized to the full. Consequently, in all the cases studied it is assumed that the mill works 23 hours a day. It should be noted, however, that in the studies carried out by ECLA on the textile industry in various Latin American countries a working-day of only 22 hours was adopted, since it was felt to be more in line with the mill conditions currently prevailing in the region.

For the purposes of the present study on economies of scale in integrated spinning and weaving mills, three products were chosen and the same eight mill sizes for each product, so that 24 different cases

/were analysed.

were analysed. By virtue of this approach, it was possible to trace the evolution of economies of scale within the size categories in relation to each product, and, in addition, to draw comparisons between different products which, as already stated, will serve various ends.

2. Main conclusions

Strictly speaking, there are no substantial economies of scale in the textile industry. Nevertheless, a large number of the mills existing in Latin America fall short of the minimum recommendable size, and by merely doubling their plant dimensions could reap the benefit of a considerable decrease in production costs.

Both in costs and in investment, economies of scale are very marked in the size category comprising mills with from 2,000 to 10,000 spindles. In mills with 10,000 to 20,000 spindles, the influence of size still makes itself felt, but to a lesser degree, and in those with 20,000 to 100,000 spindles, i.e., where the scale of production is from 10 to 50 times greater than in the first category, the reduction of costs is negligible.

The better the quality of the product - that is, the higher the yarn counts and the closer the weave of the fabric produced - the greater are the economies of scale obtainable.

For the three products studied, the following mill sizes were considered ideal: from the standpoint of savings on investment, 10,500 spindles and 630 looms for product A (coarse fabric), 10,500 spindles and 600 looms for product B (medium fabric), and 10,500 spindles and 396 looms for product C (fine fabric); and from that of savings on costs, 10,000 spindles and 450 looms for product A (coarse fabric), 10,500 spindles and 630 looms for product B (medium fabric), and 10,500 spindles and 396 looms for product C (fine fabric).

The following are the reductions in investment and costs that could be effected as between the mill sizes lowest in the scale and the ideal sizes established: in unit investment, 21, 30 and 40 per cent for products A, B and C, respectively; in production costs, 19, 27 and 40 per cent, respectively, for products A, B and C.

/Any variation

Any variation in the characteristics of the product to be manufactured in relation to those considered in the present study will mean that the ideal mill size will be the one nearest to the sizes discussed here which at the same time ensures the best possible balance between the various stages of production.

Fixed labour costs are the component in which the biggest cuts can be effected as the result of an increase in scales of production. But this item accounts for only 3 to 9 per cent of total costs in the mill size categories where the balance of production is most successfully maintained.

Next in order come variable labour costs and depreciation. However, these items, in conjunction with fixed labour costs, represent barely 17 to 25 per cent of total costs in mills of the sizes most conducive to balanced production.

The importance of idle plant capacity - inevitable at some stages of the production process because of the indivisibility of the machinery - is decisive as regards economies of scale in the smaller mill sizes, but progressively decreases until, in mills with 20,000 spindles, it is negligible. Thenceforward, the addition of a production unit at any stage of the production process, however great the idle capacity in absolute terms, will not significantly affect total production costs. In other words, the unused capital it implies represents a very small proportion of total investment. On the other hand, the higher the yarn count, the more the importance of idle capacity tends to increase. For example, in a 2,000-spindle mill the idle investment is 8.5 per cent in the case of product A; whereas for products B and C the same mill size shows indexes of 17.3 and 30.2 per cent, respectively.

For the products analysed in the present study, an ideal-sized mill, that is, one with 10,000 spindles for product A, and 18,500 spindles for products B and C, would necessitate total investment (for spinning and weaving, and including working capital) amounting to about 6.5 million dollars for the first product, 7.1 million for the second, and 4.9 million for the third. This investment could be reduced to 3.5 million, 4.0 million and 2.8 million dollars, respectively, in the size category immediately

/below, i.e.

below, i.e. in mills with 6,000 spindles for product A and 10,000 spindles for products B and C, costs per unit of output rising by only 2.5, 4.1 and 6.7 per cent for products A, B and C, respectively.

The percentage distribution of investment among its various components undergoes no substantial change as scales of production alter. Significant differences are observable, however, from one product to another; the finer the fabric manufactured, the smaller becomes the share of working capital and capital outlays during the construction of the mill.

Average costs per ring spindle - the unit of measurement in current use for comparisons of textile mills - decrease sharply as the size of the mill increases. In the case of product A, the figure drops from 144 to 114 dollars; in that of product B, from 110 to 77 dollars; and in that of product C, from 116 to 72 dollars. The same is true, although on a lesser scale, of average costs per loom.

The cost per spindle installed also falls as the yarn count rises; for example, between 8's and 40's, it decreases by 37 per cent. The cost per loom, on the other hand, is reduced by only 6 per cent in the case of product C as compared with product A.

The higher degree of processing to which product C is subjected entails heavier investment per unit of output. In mills of the optimum sizes mentioned above, the production of one unit of finer fabric implies investment 2.8 times greater than that required for the manufacture of one unit of product A. This ratio increases as the mill sizes decrease, reaching 3.7 in the 2,000-spindle mills.

The capital factors determined for the various steps in the production scale likewise denote the weakness of economies of scale in the textile industry. For the size-category ratio II/I (6,000/2,000) the capital factors obtained were 0.84, 0.75 and 0.67 for product A, B and C, respectively, but when the ratio V/IV is reached (26,000/18,400) the factor in question is equal to unity.

/Investment per

Investment per worker increases to a marked extent as the scale of production expands and, in lesser proportion, as the quality of the product improves. From 14,000 to 16,000 dollars per worker may be said to be required, on an average, for the optimum mill sizes established here.

As regards the medium product envisaged in the present study, productivity rises from 4,000 to 9,000 grammes per man/hour in spinning, and from 20 to 60 metres per man/hour in weaving, with the transition from size category I to size category VIII. Equivalent increases can be seen in the case of the other products studied.

The proportion of production costs represented by gross value added averages 31 per cent for product A, and 41 and 51 per cent for products B and C, respectively, the annual rate of return on capital taken into account in costs estimates being 12 per cent.

The product-capital ratio, at the costs level, averages about 0.26, and does not vary with the nature of the goods produced.

II. DEFINITION OF THE MILLS CONSIDERED IN THE PRESENT STUDY

1. The type of mill adopted

The present study is based on the concept of an integrated spinning and weaving mill. As is pointed out in connexion with the characteristics of the production process (see Annex), the inclusion of the finishing section would alter the nature of the study, not only on account of the technical characteristics of the process itself - which are such that it has to be carried out by means of a series of independent mills - but also because, in view of the minimum production unit sizes for finishing operations, which are utterly different from those for spinning and weaving, the economies of scale prevailing in these latter more important sections would undergo modification. Consequently, a separate study of these economies will need to be made for the finishing section, and its findings compared with those obtained for spinning and weaving. It will thus be possible to select the ideal mill size, if the establishment of a completely integrated industry is under consideration. Accordingly, the present study will relate to the manufacture of grey goods, i.e., the manufacturing process will begin with the reception of the baled cotton and end with the delivery of the grey cloth.

The basic assumption is that 3 different articles are produced in mills of 8 different sizes, and that each mill manufactures a single type of fabric; that is, 24 different cases will be analysed. In the textile industry, there are few specialized mills producing only one type of yarn and one type of fabric. The objection might therefore be raised that the conclusions reached in the present study would not be valid for mills manufacturing more than one type of product. In view of the results obtained, however, this objection is not tenable.

The main problem confronting mills which produce a large number of articles is the reduction of machine efficiency.[2/] This derives from the difficulty of scheduling production in such a way as to obviate bottlenecks

---

2/ Or, in other words, the under-utilization of machinery, as a result of both the operational deficiency and the ratio between time used and time available.

/and from

and from the frequent changes in the "production run", or "lot size", as they are currently termed. The secondary problems are those relating to the large stocks entailed, in the case of both finished products and those in course of processing. Consequently, the success of an enterprise of this type will fundamentally depend upon its ability to plan production in such a way as to avoid machine standstills that will be detrimental to the over-all efficiency of the mill.

The way in which a mill is affected by the manufacture of a larger number of products will also depend upon its size. Provided that the production flows of the individual articles are independent of one another, the whole complex will be subject to the same laws, in respect of economies of scale, as a production unit of similar size engaged in the manufacture of a single product. If the number of articles produced is so high in relation to the size of the mill as to detract from the rationality of the production flow, efficiency will be reduced and production costs will rise in proportion. As the size of the mill increases, the irrationality will become less and less marked, until the production flow is that of a perfectly balanced mill operating in much the same conditions as one manufacturing a single type of fabric. Obviously, in this case the economies of scale obtained will be greater than any that could be effected in mills of the same size whose production flow had been rational from the outset.

To sum up, no matter what number of articles it manufactures, a mill whose production programme is irrational - either by reason of bottlenecks in the production flow or because there is more than the normal delay in adapting the machinery to changes in the characteristics of the fabrics manufactured - is an unsatisfactory establishment, and cannot be taken as a basis for comparison. Similarly, where economies of scale are concerned, whatever the size of such a mill, its production costs will increase, quite irrespectively of the advantages accruing from economies of scale.

/2. Selection

2. Selection of products

Owing to the characteristics of the textile manufacturing process (see Annex), the task of selecting representative products is distinctly complex. Broadly speaking, for the purposes of the present study, fabrics meeting the following requisites may be described as representative: (a) they should be made from yarns in current production which fall within the classic categories of yarn counts - coarse, medium and fine; (b) their characteristics should correspond to those of the fabrics in greatest demand in the region; (c) they should resemble the fabrics most commonly marked in respect of yarn counts, density, width and weave structure; (d) they should lend themselves to the application of all procedures used in cotton spinning and weaving.

Accordingly, three types of fabrics were selected, which cover a wide range of production and, taken separately, may be considered representative of the type to which they belong. Their main characteristics are summed up in table 1 below (for fuller details, see Annex, table A). The products in question will be called "coarse fabric", "medium fabric" and "fine fabric", and for easier reference will be designated products "A", "B" and "C", respectively.

Table 1

MAIN CHARACTERISTICS OF THE PRODUCTS SELECTED FOR THE PURPOSES OF THE PRESENT STUDY

Specifications	Product A Coarse fabric	Product B Medium fabric	Product C Fine fabric
Type of yarn	Carded	Carded	Combed
Yarn count (warp and weft)	8	18	40
Width of grey cloth (cm)	80	90	100
Warp ends per cm	13	20	47
Filling picks per cm	10	20	32
Weight per linear metre (grammes)	140	130	130
Weight per square metre (grammes)	175	144	130

"Coarse fabric" is the material of which sacks for agricultural use are normally made; it also has its applications in industry, and in its unbleached state is used, in small proportions, for household purposes, mainly in rural areas.

"Medium fabric" is the standard weave established by ECLA in its studies on the textile industry,[3/] and may be taken to exemplify the fabrics ordinarily produced in Latin America; although its characteristics are not in strict conformity with those of a type actually on the market, inasmuch as it is an "ideal" fabric intended to represent the region's average output, it may be regarded as representative of the type which it is desired to analyse in the study of economies of scale. It corresponds to a fabric in great demand for household furnishings, dressmaking, etc., especially among the lower income groups.

The "fine fabric exemplifies a substantial proportion of the products manufactured in its category. Since fine fabrics are made from yarn whose count may be as high as 100 and over, product C clearly stands at the bottom of the scale. For that very reason, consumption of this fabric, already considerable, is expanding as a result of its great versatility, for it lends itself to the most widely different types of finishing, from bleaching to printing. It is used a great deal in making both men's and women's wear, and evidence of its adaptability is to be seen in the increasing interest shown by importers in industrialized countries, who buy it in its unbleached state to apply whatever type of finishing is in fashion in the countries concerned.

3. Selection of mill sizes

A study of the sizes of integrated spinning and weaving mills in Latin America indicates that they range from 2,000 to 100,000 spindles,[4/] while the average size varies between 4,500 and 22,000 spindles. Table 2 shows medium and maximum sizes in selected Latin American countries.

3/ ECLA, The Textile Industry in Latin America, (Vols. I to IX).

4/ For an explanation of how mill sizes are measured in the textile industry, see below.

/In all

In all the countries studied, the minimum size is 2,000 spindles, and it should be noted that the great majority of the mills fall within the smaller size categories. In Brazil and Mexico, whose cotton sectors are of outstanding importance and account for about 80 per cent of the region's installed spindle capacity, approximately 65 and 83 per cent of the mills, respectively, are found in the group with fewer than 10,000 spindles.5/

Table 2

LATIN AMERICA (SELECTED COUNTRIES): MEDIUM AND MAXIMUM SIZES OF COTTON SPINNING MILLS

(Number of spindles, in round figures)

Country	Medium size	Maximum size
Argentina	22 000	86 000
Brazil	16 500	100 000
Chile	14 000	between 20 000 and 40 000
Mexico	4 500	65 000
Peru	6 000	between 15 000 and 20 000
Uruguay	10 500	20 000

Source: ECLA, The Textile Industry in Latin America: Vol. I, Chile; Vol. II, Brazil; Vol. IV, Uruguay; Vol. V, Peru, Vol. VII, Argentina; volume on Mexico in course of preparation.

It can be seen from table 2 that the average mill size (or that obtained by dividing the total number of spindles by the total number of mills) is 16,500 and 4,500 spindles, respectively, in the two countries mentioned. This shows how large a proportion of the mills is concentrated in the lower size categories, especially in Mexico.

5/ ECLA, The Textile Industry in Latin America: Vol. II, Brazil; volume on Mexico in course of preparation.

/As already

As already pointed out, a number of problems are created by the fact that so wide a variety of textile products is manufactured. Among them are the difficulties encountered in comparing two types of fabric, if the many existing variables are taken into account. As physical output depends not only on the technical characteristics of the machinery but also on the nature of the product, the mere measurement of production - in terms of weight or volume - is of little significance. For example, a spinning mill could increase its output (measured in physical terms) from 100 to 300 units, by introducing certain adjustments in the production layout and modifying intermediate machinery requirements. Obviously, such a change-over would involve under-utilization of equipment, and therefore, in practice, mills do not take advantage of this relative flexibility to alter their production programmes. Nevertheless, the introduction of such changes is technically feasible. Owing to this peculiar feature of the textile industry, the sector has adopted the custom of measuring mill capacity on the basis of the production units installed, in contradistinction to the procedure in most branches of industry, where plant size is expressed in terms of the weight or number of units produced in a given unit of time.

The term "production units" is understood in the present study to mean those final machinery units which are used in the two separate phases of the production process: spinning and weaving. Consequently, the number of ring spindles or of looms determines the size of the textile mill. This eminently practical way of measuring mill sizes facilitates rapid comparison of the production potential of different establishments, without necessitating strict specifications of the product manufactured.

For the purposes of the present study, a size group was selected which would be sufficiently representative to preclude uncertainty as to the trends which economies of scale were likely to follow once the points established had been passed. Eight mill sizes were therefore chosen, ranging from 2,000 to 100,000 spindles. Furthermore, these categories cover virtually all the mills installed in Latin America, since the very few cases which fall outside these limits do so by only tiny margins.

In order to compare the evolution of the various products, the same scale is adopted for the three articles chosen. Scales of production are designated in accordance with the "nominal size" expressed in terms of numbers of spindles, i.e., the number of ring spindles theoretically required, in round figures. To facilitate reference to these size categories, each is assigned an ordinal number represented by a Roman figure (I to VIII).

The scales of production adopted (2,000 to 100,000 spindles) are specified in table 3. The largest and smallest mill sizes were fixed upon in the light of the criteria already indicated, in order to cover all the cases to be found in Latin America. To establish the intermediate sizes, the following principle was applied: On the basis of production of the medium fabric, three mill sizes were selected which, according to a preliminary estimate, showed the highest possible degree of balance between the various stages of production, or, in other words, the least possible idle capacity; the other three size categories were deliberately left unbalanced, the production capacity of the two biggest machines - the opener-scutchers and the slashers - being taken as the basis of calculation. The object of including the unbalanced sizes was to see how far idle plant capacity would affect economies of scale, or if in fact diseconomies of scale would result. This criterion once established, the question of mill balance in respect of the other two products was necessarily left to chance, since in view of the above-mentioned characteristics of the production process, it was impossible to ensure balance in the case of all three products at once (see again table 3).

4. Definition of the technological level adopted

After lagging for some time in the rearguard of the technological advances which marked the evolution of so many other sectors, in recent years the textile industry has undergone sweeping changes, by virtue of which it is now in a position to choose between several alternatives as regards the technological level to be adopted. The significance of this problem is all the greater in countries where labour is plentiful and capital is in short supply.

/Table 3

Table 3

MILL SIZES SELECTED AND CORRESPONDING VOLUMES OF PRODUCTION

Size Category	Nominal size (Number of spindles)	Product A (coarse fabric)			Product B (medium fabric)			Product C (fine fabric)			Scale of production
		Annual output		Number of looms	Annual output		Number of looms	Annual output		Number of looms	
		Yarn (tons)	Fabric (thousands of metres)		Yarn (tons)	Fabric (thousands of metres)		Yarn (tons)	Fabric (thousands of metres)		
I.	2 000	865	5 961	90	365	2 714	73	135	1 022	43	100
II.	6 000	2 596	17 886	270	1 133	8 416	226	405	3 067	130	300
III.	10 000	4 326	29 809	450	1 827	13 567	364	675	5 102	214	500
IV.	18 500	8 003	55 146	830	3 399	25 239	680	1 249	9 434	396	925
V.	26 000	11 248	77 503	1 170	4 750	35 273	950	1 755	13 265	560	1 300
VI.	37 000	16 006	110 292	1 660	6 797	50 478	1 360	2 498	18 870	800	1 850
VII.	60 000	25 956	178 850	2 700	10 962	81 399	2 190	4 050	30 602	1 280	3 000
VIII.	100 000	43 260	298 084	4 500	18 270	135 658	3 650	6 750	50 998	2 140	5 000

In the textile industry, the aim of technological research has been to make yarn production a continuous process, but despite the great progress achieved, everything seems to suggest that it will be some time before this objective can be attained. On the other hand, the process of manufacturing yarn has been considerably simplified, automation of the series of operations required to convert it into fabric has taken place on a large scale, and controls have been introduced by means of which it has been possible to increase the production capacity of textile machinery. The analysis of these problems is outside the scope of the present study, and will be dealt with in another ECLA report.6/

In selecting the equipment on which this study could be based, a position which might be described as conservative was adopted; that is, machinery was chosen which, although regarded as up-to-date, is not characterized by the very latest technological innovations in the field of automation. A definition of this technological level will next be given, together with an explanation of what is understood by "up-to-date machinery" in the present study.

The definition of the technological level of the production process must be fundamentally based on specifications of the technical characteristics of the machinery, in order to clarify the following points: (a) the degree of automation of the process, i.e., the greater or lesser extent to which manual operations are involved in tending the machines and in the transport of the product in process of manufacture; (b) the production capacity of a given machine, once operational conditions have been established, i.e., the nature of the products (yarn count, twist, etc.), the quality of the raw material, atmospheric conditions (humudity and temperature), etc.; (c) the quality of the product obtained; and (d) the amount of maintenance work required.

These specifications are outlined in table 4, which is considered adequate in view of the scope of the present study.

6/ Choice of techniques in the textile industry (in course of preparation).

/Table 4

Table 4

TECHNOLOGICAL CHARACTERISTICS OF THE PRODUCTION PROCESS ADOPTED

Machine	Main technical characteristics	Number of production units per machine	Production capacity	Level of automation	Cleaning and lubrication systems
Openers/scutchers	Pneumatic delivery of cotton; single-process scutcher; dust removal by filter bags	1	Maximum output: 200 kg per hour	Openers fed by hand; hand lap doffing	By hand
Cards	Rigid clothing; 16"-diameter sliver cans	1	Maximum output: 25 kg per hour	Laps fed by hand; sliver cans changed by hand	Pneumatic waste removal; centralized pressure lubrication
Lap machines	Wide laps; doublings of 16 slivers	1	Operational speed: up to 1 600 feet per minute	Hand doffing	By hand
Combers	Duplex machine with 8 heads; 14"-diameter sliver cans	2	Operational speed: 140 nips per minute	Sliver cans changed by hand	Cleaning by hand; centralized pressure lubrication
Drawing frames	Controlled draft system; doubling of 6 slivers; 16"-diameter sliver cans	2	Operational speed: between 400 and 800 feet per minute	Sliver cans changed by hand; automatic stop motions set in operation by sliver breaks, over-feeding of rollers and filling-up of sliver cans	Pneumatic waste removal; centralized pressure lubrication
Roving frames	Controlled draft system; 14" lift and 6" bobbin diameter	Minimum, 36 spindles; variable by fours	Maximum operational speed: 1 200 spindle revolutions per minute	Hand doffing	By hand
Ring spinning frames	Swivel-arm drafting system or equivalent; 11" lift, and ring diameters up to 2 1/4"; pneumatic broken end collectors	Minimum, 360 spindles; variable by fours	Maximum operational speed: 12 000 spindle revolutions per minute	Bobbins fed by hand; hand doffing	Cleaning by hand, centralized pressure lubrication
Cone winders	Grooved drum system	Minimum, 24 spindles; variable by fours	Winding speed: up to 700 yards per minute	Hand bobbins changing and cone doffing; manual tying-in; automatic transport of empty bobbins	By hand
Pirn winders	-	Minimum, 12 spindles; variable by sixes	Operational speed: up to 10 000 revolutions per minute	Automatic pirn changing; empty pirns fed into magazines by hand	Cleaning by traveller blowers; lubrication by oil bath and centralized pressure pump
Warpers	Metallic beam; hydraulic warp stop motion, automatic package changing	1	Operational speed: up to 600 yards per minute	Automatic stop motion for yarn breaks; hydraulic beam removal system	By hand
Slashers	Multi-cylinder type; controlled yarn tension	1	Evaporation capacity: 320 kg per hour	Automatic temperature, humidity and size level controls	By hand
Looms	Automatic pirn change system; controlled warp tension	1	Operational speed: 200 picks per minute	Automatic weft feeding; automatic stop motion in case of warp and weft breaks	By hand

/To complete

To complete the definition of the technological level adopted, equipment specifications must be supplemented with certain important indexes relating to workloads, productivity, investment and manpower. These indexes are presented in tables 5, 6 and 7, together with others on value added and the product-capital ratio, which may be of use for different purposes. It should be noted that the workload coefficients in these tables do not include administrative staff or auxiliary services personnel (see tables 5, 6 and 7 and figures I, II and III).

The change observable in the rate of increase of some of the indexes is attributable to the fact that in unbalanced mills it is impossible to establish a manning-table strictly proportional to the equipment required. It will also be seen in tables 5, 6 and 7 that the workload does not exactly correspond to the quotient of unit production and productivity, owing to the series of roundings effected in order to arrive at the indexes of operatives per thousand spindles or per hundred looms.

Table 5

PRODUCT A (COARSE FABRIC): MOST IMPORTANT COEFFICIENTS AFFECTED BY THE TECHNOLOGICAL LEVEL OF THE PRODUCTION PROCESS

Concept \ Size category and number of spindles	I 2 000	II 6 000	III 10 000	IV 18 500	V 26 000	VI 37 000	VII 60 000	VIII 100 000

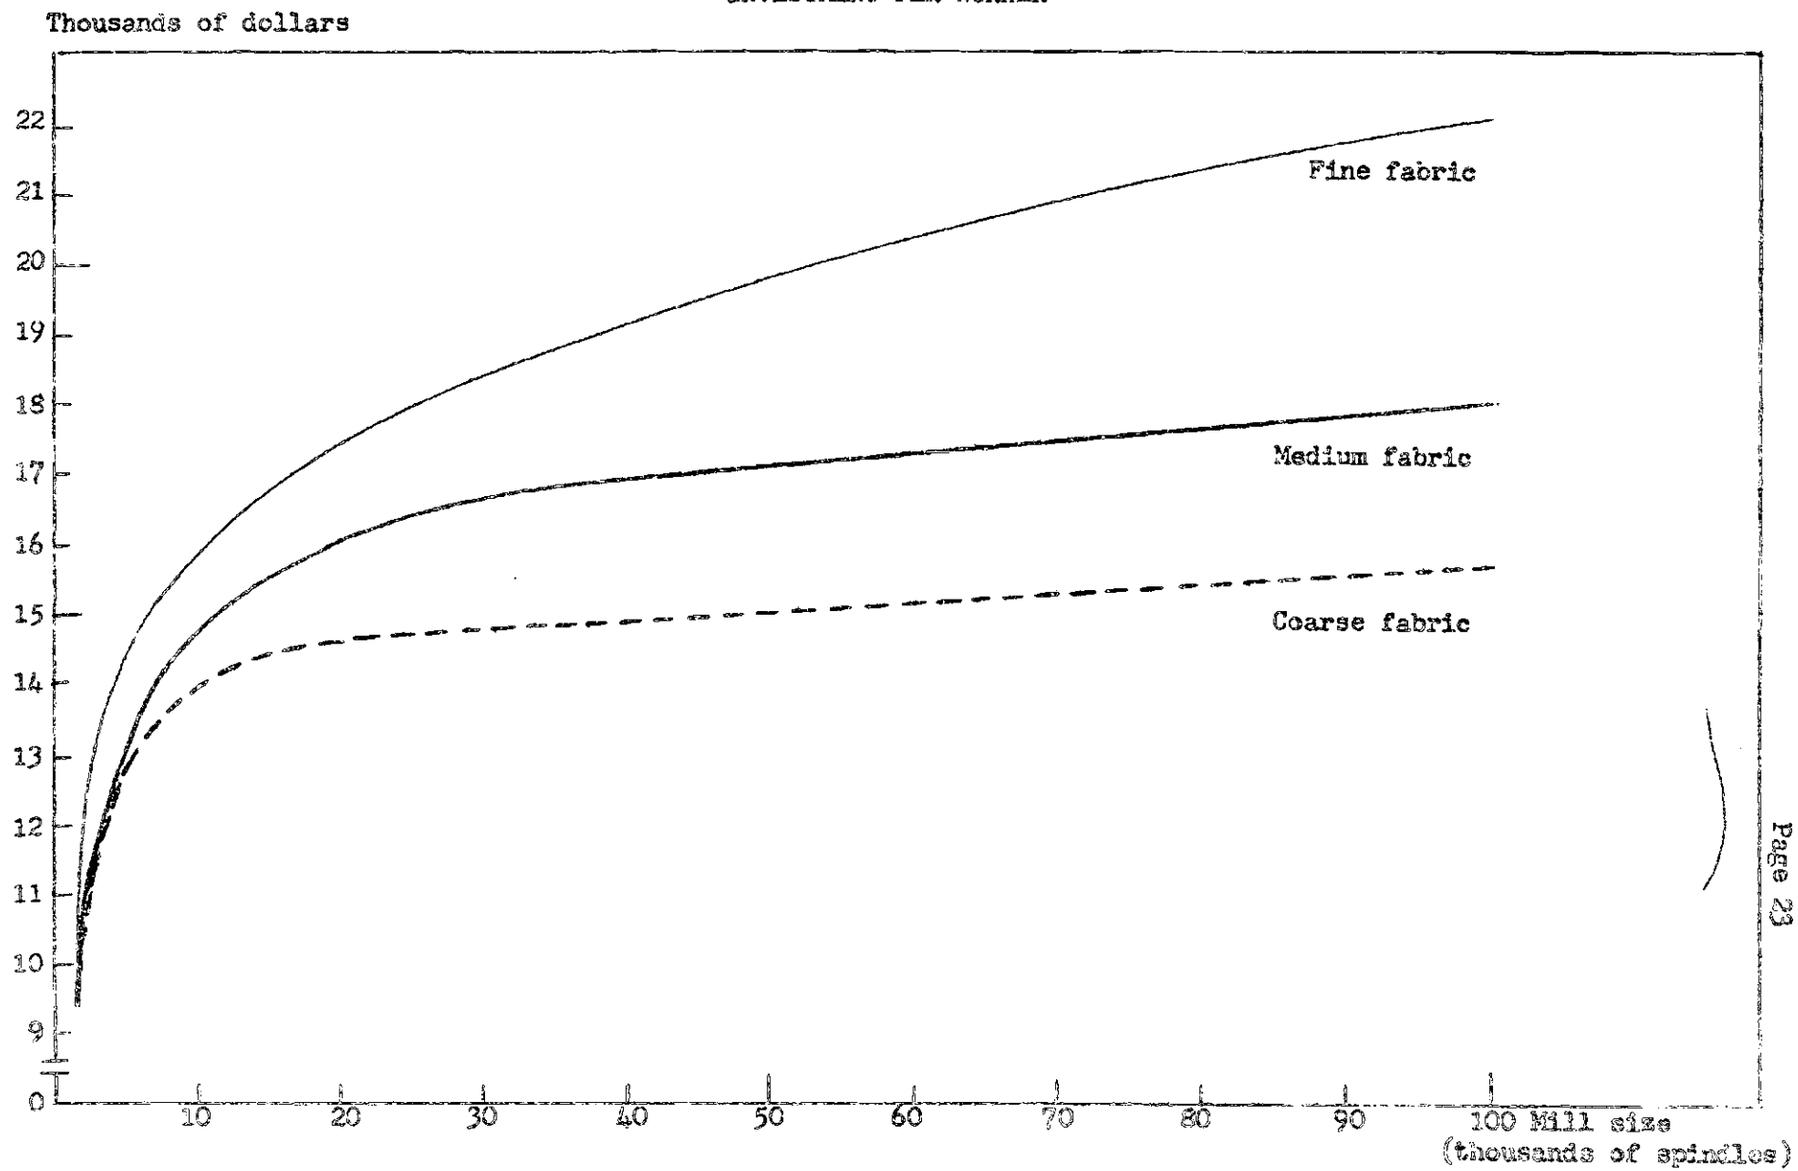
INVESTMENT PER WORKER



III. MILL STRUCTURE

1. Investment requirements

The production plans outlined in tables B, C and D indicate the operating conditions for each product. With these plans as a basis, tables E-Z were then prepared in which daily output, consumption of raw materials, amount of waste recoverable and machinery required to carry out the production programme were specified for each mill.

These tables also indicate the margin of unused machine capacity per unit, in other words the amount of time each machine must operate for the purposes of the production programme, and the total number of working hours on a three-shift basis (23-hour day). It has been assumed, wherever possible, that the machines whose minimum size exceeds mill requirements would operate for less than three shifts. This reduction in working time would not of course modify the amount of machine capacity standing idle, but would enable the number of operatives to be cut proportionately and thereby lower production costs.

Tables AA, BB, CC, DD and GG indicate the volume of investment needed in each case studied. Table EE sets forth the criteria adopted for determing the quantity of working capital required, while table FF gives the installation periods estimated for the different mill projects according to each one's size and manufacturing processes.

The machinery prices adopted were those quoted by long-established textile machinery manufacturers for July 1965. To simplify matters, the total cost of the machinery was worked out in terms of one unit of production.[7/] Strictly speaking, the number of machines required should be calculated from the number of individual production units that make up one machine, and the cost estimates drawn up on that basis, since unit cost depends on how many units there are to each machine. This method

---

7/ The term "unit of production" should be taken to mean each of the mechanical elements that includes a component for the delivery of product. Scutchers and cards, for instance, have only one production unit, whereas drawing frames, roving frames and ring spinning frames have several, that vary in number according to the needs of the individual mills.

would, however, entail cost consultations after the mill structure had been decided upon, which would be materially impossible. To put it plainly, this degree of elaboration adds nothing to the quality of the calculations, and is simply mentioned here in a spirit of precaution in case this type of methodology is chosen for project preparation.

As regards fixed investment, the sums earmarked for covering the expenses of the mills' entry into operation were proportionate to the time needed for setting them up. The interest payable during the period of construction was estimated to be 12 per cent annually during the project implementation periods noted in table FF; it was also assumed that when half that period had elapsed, at least a part of the mills, depending on their particular size, would be in operation (see table GG). The cost of sites, vehicles, special fittings such as fire sprinkler systems, or internal communications has not been included in the investment figures.

2. Production costs

Tables LL, MM and NN set forth the production costs for each case under consideration. To facilitate analysis, the costs were divided into fixed and variable in keeping with the main criteria adopted for defining the various cost factors involved.

(a) Raw materials

The prices of the cotton grown in different Latin American countries were reviewed, and the types singled out that were technically and economically best suited to the products to be manufactured. Table 8 lists the prices of cotton grown in the three major Latin American producers (1963-64 crop).

Table 8

AVERAGE PRICE OF COTTON, C.I.F. LIVERPOOL, CROP 1963-64

Type of cotton				Dollars per kg
Brazilian -	Paulista	1 1/32"	(26 mm) type 5	0.56
	Sertão	1 3/16"	(28/30 mm) type 4	0.60
	Seridó	1 3/8"	(36 mm) type 3	0.68
Peruvian -	Pima	1 9/16"	(40 mm)	0.93
Mexican -	Matamoros	1 1/16"	(27 mm)	0.65

Source: Stock Exchange quotations.

The prices quoted in the present study relate to the three classes of Brazilian cotton fibre - short, medium and long staple - that meet the requirements of the fabrics to be manufactured. Peruvian Pima, being of high quality and therefore more expensive, cannot justifiably be used to produce the 40's yarn selected for this study and is best reserved for the manufacture of combed yarns with a finer count. Mexican Matamoros cotton is quoted as having a fibre only 27 mm long, but is recognized as a possible replacement for Brazilian Sertão in the manufacture of 18 count yarn. As the raw Matamoros is fairly expensive, however, the inclusion of this type tend to throw the relationship between the three kinds out of proportion.

Allowance was made in calculating the real cost of the raw material for the waste produced during each process (see table 9). This was estimated either as partially recoverable or at the residual value it can usually fetch on the market in relation to the cost of the raw cotton With this method of cost accounting it is obvious that receipts from the sale of the waste cannot be reckoned as part of the enterprise's income

Table 9

ACTUAL COST OF THE COTTON USED IN MANUFACTURING THE DIFFERENT PRODUCTS

(Dollars per kilogramme)

	A Paulista	B Sertão	C Seridó
Price of raw cotton	0.560	0.600	0.680
Real waste (percentage) a/	9	11	28
Price of processed cotton	0.615	0.674	0.944
Less:			
Sales value of waste b/	0.007	0.010	0.057
Actual cost of cotton	0.608	0.664	0.887

a/ See Annex, tables E-Z.

b/ Estimated as 15 per cent of the purchasing price for Paulista and Sertão and 30 per cent of the price for Seridó.

It should be pointed out that waste is invariably calculated as a percentage of the total weight of the raw material fed into the machine and not of the ensuing product. The proportion recovered for further use varies according to the type of product made, being 8.7 per cent in the case of coarse fabrics, 5.3 per cent for medium fabrics and 2.7 per cent for fine fabrics (see Annex, tables E-Z).

(b) Labour

Tables HH, II and JJ indicate the number of workers needed to keep the mills operating on a three-shift basis, with their yearly wages. Instead of the customary classification of labour as direct or indirect, it was decided to divide them into fixed or variable so as to keep more faithfully to the criterion used for the cost classification. For the purposes of determining manpower costs the minimum wage was calculated on the basis of an examination of the prevailing wage rates in the textile industry in a few Latin American countries. The findings are set out in table 10.

/Table 10

Table 10

AVERAGE WAGE OF UNSKILLED LABOUR IN THE TEXTILE INDUSTRY IN FOUR COTTON-MANUFACTURING LATIN AMERICAN COUNTRIES

(Dollars per hour)

	Direct labour	Indirect labour
Brazil	0.36	-
Colombia	0.34	0.27
Mexico	0.35	0.25
Peru	0.36	0.23

Source: ECLA, The textile industry in Latin America, Vols. II. Brazil, III. Colombia, V. Peru (XI. Mexico, unpublished).

As table 10 shows, manpower costs, whether relating to direct or indirect labour, vary little among the four countries considered. The figures were used as the basis for a wage scale (see table 11) classifying the labour force as skilled, semi-skilled or unskilled, which thus provides a clearer picture of the types of labour needed in the mills and the appropriate wage rate for each category.

Table 11

WAGE SCALE ADOPTED IN THE PRESENT STUDY

(Dollars)

Classification	Hourly wage
Unskilled	0.25
Semi-skilled	0.35
Skilled	0.50
Foremen and supervisors	0.75

/As the

As the minimum wage for unskilled labour was taken to be 0.25 dollars an hour and for semi-skilled labour 0.35 dollars, which is 40 per cent more, it was assumed that skilled operatives and supervisors would receive 100 and 200 per cent more, respectively.

The concept of semi-skilled labour as used in this study stems from the fact that a machine operative in the textile industry is rarely a skilled workman in the true sense of the term since he can be trained in the mill itself in three to six months. He is however, at a higher level than the mill hand who helps him by moving materials, for instance, and has never had any kind of training. Then, too, a machine tender is paid in proportion to his output, since he is in direct charge of the machine, and thus earns a higher wage than the legal minimum received by the unskilled hands.

Social security charges were reckoned to be 40 per cent of the labour costs, which is the usual proportion in most Latin American countries.

(c) Capital costs

Depreciation costs were computed on the assumption of a useful life of forty years for buildings and of fifteen years for machinery. Production costs include payment of 12 per cent annual interest on the capital invested.

(d) Other cost components

The criteria adopted for determining the other production cost factors are explained in the footnotes to tables LL, MM and NN. It merely remains to point out that no insurance or taxes and charges of any kind were included in the costs as they vary too widely from one country to another.

IV. ANALYSIS OF RESULTS

1. Economies of scale in investment

Before economies of scale as such are discussed, a glance should be taken at the behaviour of certain figures that are indicative of investment composition. The same figures can be used to compare mills that are of different size and structure and consequently manufacture different kinds of fabric.

(a) Idle machinery capacity

Because of the indivisibility and relatively high minimum size of some textile machines, it is not always possible to establish a perfect balance between the different production stages. The fact that some machines are standing idle during part of the working day means that not all the investment is being used and this, in turn, affects production costs. In order to determine how far the existence of idle capacity affects economies of scale, a table was prepared giving the figures for idle investment for each case under consideration (see table 12 and figure IV).

Idle capacity was calculated in relation to the total time available for using the machinery, in other words, the working day of 23 hours fixed for the mill as a whole. For the stages in which there is a great deal of idle capacity, the working day could be shortened to one or two shifts; this would also reduce manpower costs, although this was not taken into account in calculating idle investment. Under-utilization of the machinery would thus enable the number of workers to be reduced proportionately without any adverse effect on production costs except for depreciation. The idle capacity that is bound to exist when the machines are indivisible will tend to disappear as mill size increases and a coarser yarn count is manufactured. In mill size I idle capacity is 8.5 per cent for product A, but 17.3 and 30.2 per cent for products B and C. In the three largest sizes considered, idle capacity shrinks to little or nothing for products A and B, although a certain amount remains in the case of product C.

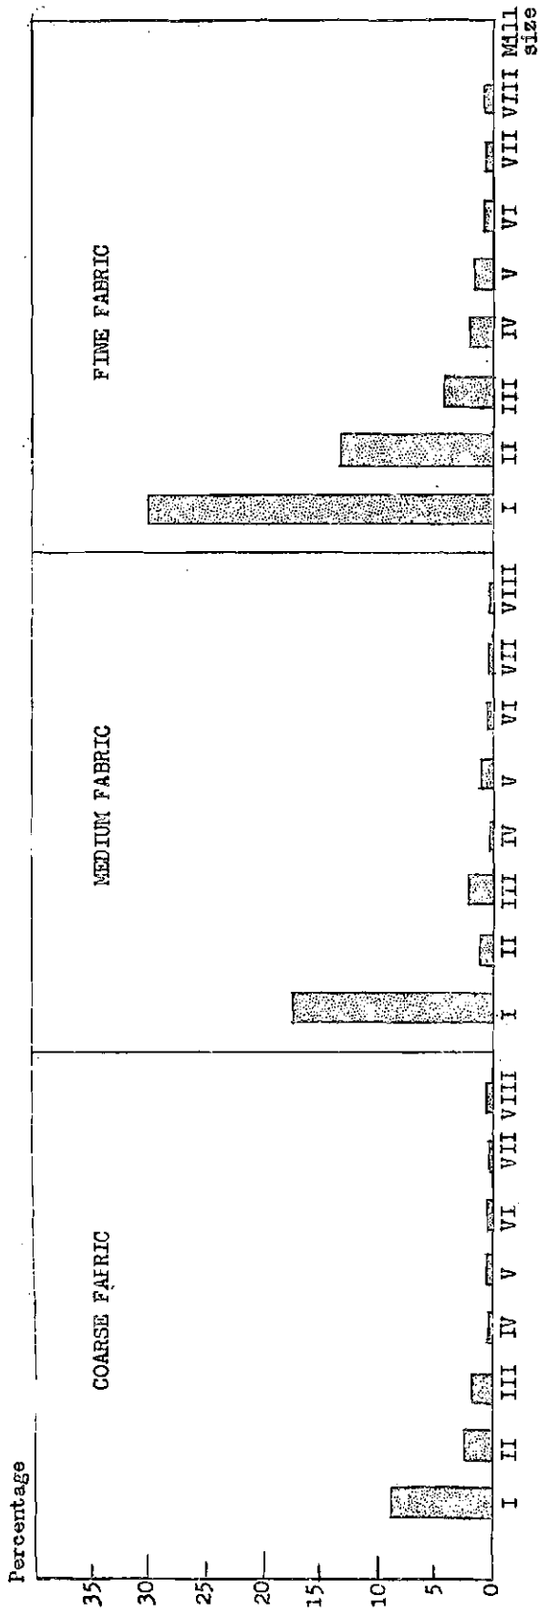
Figure IV

IDLE CAPACITY AS A PERCENTAGE OF TOTAL INVESTMENT



/(b) Percentage

(b) Percentage distribution of investment

It is clear from table 13 that the percentage distribution of investment components tends to remain much the same as mill size increases, but changes appreciably between one product and another. For instance, both working capital and the amount of interest paid during the period of construction are considerably reduced when fine instead of coarse fabrics are made. This is mainly because the volume of raw cotton and material in process of fabrication is smaller, and mills for producing fine cloth can be built in a shorter space of time (see table 13 and figure V).

(c) Unit cost of machinery

This means the average cost per final unit of production involved in a particular process, that is, per ring spindle in the spinning mills and per loom in the weaving mills, the cost in each case being that of all the machines and accessories installed in the section concerned. Maintenance workshops, laboratories and other items, presented under the head of "miscellaneous" in tables AA, BB and CC, are therefore not included in unit cost.

Average cost per spindle drops sharply as mill size increases for the three sorts of product studied, falling from 144 to 114 dollars for product A, from 110 to 77 dollars for product B and from 116 to 72 dollars for product C. These reductions of 20, 30 and 38 per cent are mainly observable in the first three sizes on the scale, namely, between mills of 2,000 and of 10,000 spindles. From the 18,500-spindle category upwards, there is practically no reduction to be seen. The cost per loom in the weaving and preparation sections varies in the same fashion as the cost per spindle, though less markedly, the reductions for products A, B and C being 10, 19 and 31 per cent respectively.

The foregoing data are set out in table 14, which shows that in some cases the unit cost of production goes up instead of down as mill size expands. As already pointed out, this is due to a lack of balance in certain sizes. The yarn count produced also plays an important part in determining unit cost in the spinning mills, a reduction of about 37 per cent being obtained on switching from 8's to 40's. Although three

a/ Not including the value of the equipment placed under the head of "miscellaneous" in tables AA, BB and CC.

/additional stages

additional stages - pre-combing drafting, lap forming and combing - are needed to manufacture 40's yarn, the increased machinery requirements for producing coarse yarn raise investment per unit of production. In the weaving mills, however, the unit cost drops much less between the two kinds of product, the difference being barely 6 per cent.

(d) Fixed investment per square metre

Another yardstick often used for comparing textile machinery is the ratio of total mill cost to the building acreage. Table 15 gives the cost of the fixed investment per square metre of area built over and the unit cost of the buildings themselves.

The cost of the buildings per square metre, including such ancillary installations as power and light, air conditioning, water and steam remains virtually the same (66 - 68 dollars) throughout the production scale and for all three products manufactured.

Total fixed investment per unit of area, on the contrary, changes considerably between the 2,000 and 100,000-spindle categories, increasing from 315 to 449 dollars (42 per cent). This shows that better use is made of space in the larger mill sizes. For products B and C in the largest and smallest sizes investment per square metre rises from 47 to 54 per cent, which indicates that in the smaller sizes there is more wastage of space the finer the article produced.

(e) Investment per unit of output

Economies of scale in investment are inclined to vary in accordance with the type of product manufactured, increasing as the fabric becomes finer. This indicates that idle capacity has a fairly marked influence on the value of investment per unit of output; in fact, the balance between the different production stages is more easily achieved the larger the mill and the coarser the cloth produced. Consequently, once a mill has a balanced production flow, unit investment is difficult to reduce even when the production scale is stepped up.

The fact that a fine cloth has to go through more processing stages raises investment per unit of output. The difference in unit investment between coarse and fine fabric therefore becomes greater as mill size

a/ Including cost of buildings, and power, light, air conditioning, water and steam installations.

decreases, precisely because the disequilibria are more pronounced in the small mills turning out fine fabrics. For instance, in a 2,000-spindle mill, the investment needed to produce 1,000 metres of fabric C is 3.7 times greater than for the same amount of fabric A. From the 18,500-spindle level upwards, however, it is only 2.8 times more.

It has been stated that economies of scale in investment increase in proportion to the fineness of the yarn and fabric produced, since the difference in unit investment between the largest and smallest mill sizes is greater for fine than for coarse cloth. Even so, the most economic size from the standpoint of unit investment is reached at almost the same point on the production scale for the three types of fabric under consideration. As table 16 shows, the maximum reduction for all three is attained in the 18,500-spindle size, which is equivalent to 830 looms for the coarse cloth, 680 for the medium and 396 for the fine cloth. At this point on the scale, unit investment is 21, 30 and 40 per cent less for products A, B and C than in the smallest size (2,000 spindles) whereas the reductions obtainable between the two extremes of the scale are only a shade larger, being 24, 32 and 42 per cent respectively. Consequently, from size IV onwards, there are practically no further economies obtainable in investment, and the ideal size is to be found between the 10,000-spindle and 18,500-spindle categories at whatever point the best possible balance can be attained for the mill's particular end product (see figure VI).

These conclusions are borne out by the capital factor[8/] calculated for different points on the scale. The ratio of this factor in size II to that in size I (output being three times as much in the former) is 0.84, 0.75 and 0.67 for products A, B and C respectively; in other words, the economies of scale increase as the fabric becomes finer. But the value of the capital factor for size V in relation to that for size IV

8/ Value of α in the equation $\left(\frac{P_1}{P_o}\right)^{\alpha} = \frac{K_1}{K_o}$

in which P_o, 1 = production at two points on the scale.

K_o, 1 = total investment at those points.

The capital factor is also known as the coefficient of proportionality and can be used in analysing production costs.

is almost the same for all three products, which means that from size IV upwards investment is strictly proportionate to output. Table 17 lists the capital factors obtained at three points on the production scale for the three fabrics under consideration.

A comparison of the figures given in table 17 with their equivalents for other branches of industry show that the economies of scale obtainable in the textile industry are very small. In the chemical industry, for instance, the value of the capital factor was found to vary between 0.50 and 0.80, the most frequent coefficient being about 0.60, which could be attained simply by trebling production.9/

2. Economies of scale in costs

Before the trend of production costs is reviewed in relation to mill size, the percentage distribution of costs among the different factors of production should be looked into. Table 18 summarizes the figures obtained for the three products in the two mill sizes at either end of the scale and in an intermediate size, thus making it possible to assess the changes brought about in some cost components by an increase in the production scale. These changes are substantial in the first four mill sizes but insignificant from size V upwards, the same point at which economies of scale can no longer be obtained in investment.

The nature of the textile fabric is particularly important for the structure of production costs, since the share of fixed costs tends to increase as the fabric becomes finer. This explains, of course, why economies of scale are greater in the case of fine goods.

The raw material is the major cost component in a textile mill, constituting in the case of coarse fabric 62 per cent, medium fabric 51 per cent and fine fabric 41 per cent of the total production costs. As the volume of raw material used in the process of manufacturing will not be reduced by enlarging mill size, the economies of scale must necessarily be made in some elements of fixed cost, more particularly fixed labour. Next to raw material in order of incidence come financial charges, which comprise depreciation and the payments of interest on the total capital invested. The share of these in aggregate costs expands from 20 to 34 per cent if fine instead of coarse fabrics are manufactured. Since they are in strict proportion to the amount of capital invested and it has been found that no appreciable reduction can be made in investment by raising output, there will clearly be no cut in financial costs. Given that the raw material and the financial charges together account for 78 to 82 per cent of the over-all production costs, the whole effort to cut down on such costs must be directed towards the remaining components which constitute only 18 to 22 per cent (see figure VII).

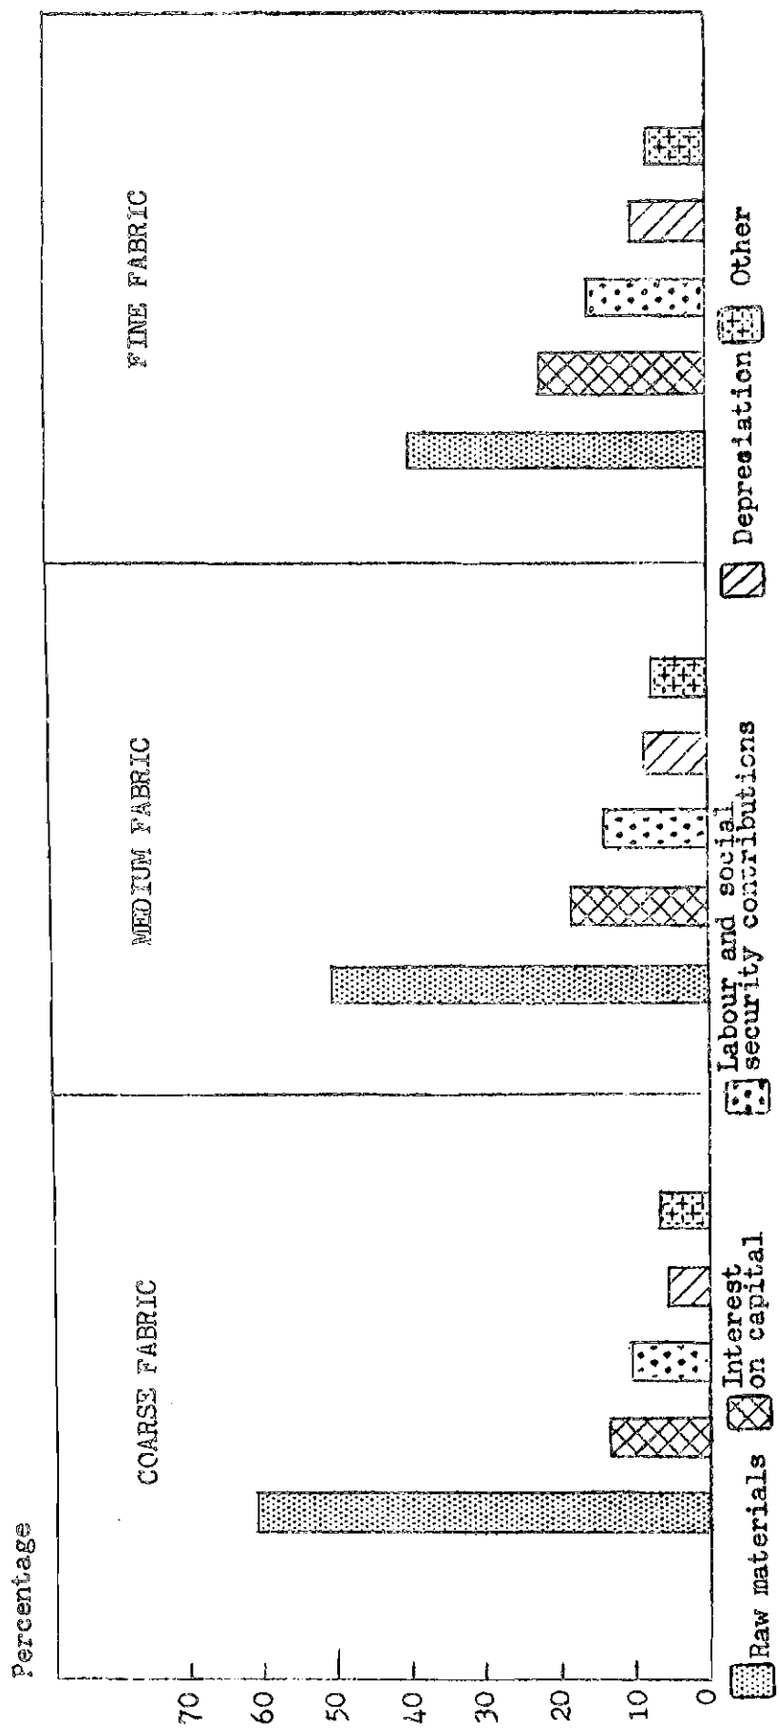
Figure VII

PERCENTAGE DISTRIBUTION OF PRODUCTION COSTS
(Size V)



The unit cost of production which, in this study, is calculated per metre of cloth manufactured, displays much the same pattern as unit investment, reductions of 22, 29 and 43 per cent being recorded respectively for products A, B and C between the smallest and biggest mill sizes, i.e., the lowest level of output is increased fifty-fold. The optimum size for costs does not necessarily fall at the same point on the production scale for the three types of fabric. Unit cost remains virtually the same from size III upwards for product A and from size IV upwards for products B and C (see table 19 and figure VIII). Consequently, from the cost standpoint, the optimum mill size is somewhere around that of 10,000 spindles for product A and 18,500 spindles for B and C, since unit cost in those categories is respectively 19, 27 and 40 per cent lower than in the first size.

The cost components that influence economies of scale are set out in table 20. Fixed labour[10/] shows the most substantial reduction in cost, amounting to approximately 80 per cent between the two extremes of the production scale for all three fabrics.

Variable labour costs, on the other hand, are 37 per cent less between the two ends of the scale for coarse fabrics but 69 per cent higher for fine cloth. This is due to the fact that small mills turning out fine goods find it harder to distribute their labour force rationally and to make full use of them. The two elements in financial charges, namely depreciation and interest on capital, also show reductions that increase in proportion to the fineness of the end product, and range from 23 per cent for product A to nearly 40 per cent for product C. It is clear that extensive reductions can be made in the costs of fixed and variable labour as well as in financial charges, and their influence on the economies of scale might well be decisive were it not for the fact that they represent such a small fraction of the total production costs. Even so, if interest on capital (which plays a very flexible part in costs since it is reckoned as a profit for the enterprise) were deducted from these two components that account for 31 to 48 per cent of the total[11/] they would shrink to only 17 and 25 per cent respectively (see figure IX, X and XI).

10/ Including the corresponding social security charges.

11/ Labour calculations include social security charges.

VIII.	100 000	2 140	5 000	58	57	0.5	25 691

a/ Ratio of unused to total investment, (see table 12).

In short, the decisive cost components in economies of scale in the textile industry are fixed labour, variable labour and depreciation. As the three depend on installed capacity and the investment tied up in this, it is clear that, although the under-utilization of certain machines may have only a slight effect on aggregate investment, nevertheless one of the basic conditions for lowering production costs is the achievement of a balanced production flow throughout the stages of mill processing.

The other cost components susceptible of reduction are upkeep, overheads and ancillary materials, which can be realigned so as to bring about a substantial cut in the cost of certain enterprises. But as they constitute no more than 3 or 4 per cent of the total production costs in the case of a rationally organized mill, they will never have a decisive effect on the enterprise's savings and far less so on its economies of scale.

As pointed out earlier, machinery is under-utilized in some of the production stages, but this is often unavoidable even in well-designed projects. The findings of the present study demonstrate that once a particular mill size has been reached, which will vary from one product to another, idle capacity becomes insignificant as the addition of one machine has little effect on total investment after the volume of output has passed a certain point.

The results obtained are summed up in tables 21, 22 and 23, in which the index of idle capacity represents the ratio of unused investment to the total investment needed to operate a mill. These figures show that the optimum sizes, namely, those in which the unit cost can be slashed to the minimum and unit investment is also susceptible of reduction, are 10,000-spindle mills in the case of product A and 18,500-spindle mills for products B and C. Over and above these sizes the reductions are too small to make it worth while mobilize the large sums of capital needed. However, the investment required for the most economic mill size could be appreciably reduced with very little difference in production costs.

If the next smallest mill sizes, i.e. 6,000 and 10,000 spindles, are chosen instead, the investment requirements for products A, B and C would drop from 5.6, 7.1 and 4.9 million dollars to 3.5, 4.2 and 2.8 million respectively, the rise in the unit cost of production being barely 2.5 per cent for product A, 4.1 per cent for product B and 6.7 per cent for product C.

/Despite the

Despite the fact that the cotton textile industry does not offer wide possibilities for economies of scale, problems relating to the choice of mill size still occur over a fairly wide stretch of the production scale. A glance at the principal mill sizes in Latin America[12/] will show that most of them are smaller than the optimum sizes determined in this study. Although, in planning the establishment of a mill, such factors as the volume of over-all investment must be taken into account as well as production costs, the majority of the Latin American mills unquestionably need rescaling as regards the minimum size at which a reduction of any significance can be made in production costs.

12/ ECLA, The textile industry in Latin America, op. cit., Vols. I-IX.

Annex

CHARACTERISTICS OF THE SPINNING AND WEAVING PROCESSES

The physical transformation process to which natural fibres are subjected in order to convert them into woven goods, although simple as regards the mechanical principles on which it is based, involves the use of a large number of machines. The process of manufacturing a fabric can be divided into two entirely separate stages: (a) the production of yarn, or, in other words, the transformation of the tufts of fibre into a continuous spiralled bunch, held together by the frictional force of the twist they are given; and (b) the production of the fabric proper, which consists in combining the threads in such a way as to obtain a flat surface, more or less closely woven, with adequate tensile strength and resistant to wear and tear.

The basic problem in the manufacture of cotton yarn is that of laying the fibres parallel to one another and forming them into a continuous rove of predetermined diameter. In modern methods of spinning, this stage is preceded by 5 to 8 operations, completely independent of one another. The next concern is how to apply the twist to the fibres once and for all in such a way as to maximize the strength of the yarn in the case of a given diameter[a/] and a specific quality of raw material. The tensile strength of a particular yarn depends upon various factors, of which those worth mentioning for the purpose of the present explanation are the twist it is given and the length of the fibres composing it. This point merits rather more detailed consideration.

---

a/ The "diameter" of the yarn is a manner of speaking; a particular yarn is identified by the "count", which is the ratio between a given length and the corresponding weight. In the so-called "indirect yarn count systems" (English and metrical), which are those most commonly used for cotton, the higher the count the finer is the yarn. The actual diameter of the thread depends not only upon the mass of fibres forming it - i.e., the yarn count - but also on the thickness of the fibres themselves and on the twist received.

/Cotton fibre

Cotton fibre is one of the most variable materials used at any point in the textile industry. The properties of cotton fibres, and above all its staple length, vary according to the area of cultivation and the climatic conditions, and may even be different for two crops from a single area. Moreover, in any given stock of cotton the fibre-length variations in relation to the standard for the stock are not the same. This means that if the fibres in a given sample were sorted and laid side by side with the longest fibres on the left, a typical pattern would be obtained, and this pattern varies from one stock of cotton to another, reflecting the fact that the variations from the norm is not the same. Put more simply, the longer the staple and the more even the distribution of the fibres by length, the higher the count and the greater the relative strength of the yarn obtainable.

Thus, the unevenness of the length of the cotton fibres in their natural state conditions both the counts and the strength of the yarn that can be manufactured. To overcome this difficulty, and widen the range of yarn counts that can be produced, while at the same time improving the other physical characteristics of the yarn (strength, uniformity, appearance, etc.), a mechanical procedure has been introduced whereby a specific proportion of short fibres can be removed, with the result that the average length of the fibre is increased, dispersion among different lengths is reduced and the lot is rendered homogeneous. This procedure is known as "combing" the fibres, and the yarn produced in this way is called "combed yarn"; whereas yarn which has not been subjected to the combing process is described as "carded". The combing of cotton makes yarn production costs very much higher, either because more processing is entailed or because in the removal of the short fibres sometimes as much as 30 per cent of the raw material is eliminated in the form of waste, in addition to the normal waste involved in carding and combing, which represents about 14 per cent.

A study of table ÑÑ will obviate the need for a very detailed description of the various phases of the production process in the cotton textile industry. The table in question shows the production flow chart for one of the cases considered in the present study (C-VII), and provides

/a picture

a picture of all spinning and weaving operations, from the arrival of the baled cotton to the delivery of the grey goods. The flow chart relates to combed yarn; in the manufacture of carded yarn, the pre-combing operations are omitted, and the rest remain unchanged.

Since the various yarn counts and thicknesses may be combined in innumerable different ways in the composition of the fabric, and other concomitant characteristics may vary in their turn, the range of products in the textile industry is so wide as to preclude any sort of generalization with regard to the production capacity of a given machine or plant. Although a fairly accurate estimate can be made, the validity of any comparison of production capacities will depend upon precise specification of the nature of the products manufactured. In this connexion, it will be useful to give a brief explanation of the way in which production is usually measured in the textile industry in the two stages of the manufacturing process - spinning and weaving.

Yarn output is measured by weight, the count produced being also specified. As a spinning mill usually manufactures more than one count at a time, it is necessary to specify the average count, that is, the average for the yarns produced, weighted by the output of each. When comparisons are made, the first problem stems from the fact that operational conditions in a mill producing, for example, four different counts will not be the same as in another producing a single count, even though the average count may be the same for both mills.

The production capacity of a spinning mill is determined by the number of ring spinning frames it possesses, while the output of these frames will in its turn depend upon the following factors:

(a) Yarn count produced, i.e., the mass of fibres comprising one unit of length;

(b) Yarn twist, i.e., the number of turns the thread has been given in one unit of length. The twist is expressed as the ratio between the number of turns performed by the traveller[b/] and the length of the yarn produced in a given unit of time;

---

b/ The number of turns the traveller performs round the ring is equivalent to the number of spindle revolutions minus the quotient resulting from division of the length of yarn produced in a given unit of time by the length of the ring perimeter.

(c) Machine speed, generally expressed in terms of spindle revolutions per minute;

(d) Operational efficiency of the machine, i.e., the ratio between operating time and the total time available, due allowance being made for the fact that the whole machine or some of the spindles will undergo occasional stoppages on account of yarn breaks, bobbin changing, emergency repairs or maintenance operations, faulty machine-minding, etc. Machine efficiency can be more precisely defined as the ratio between real and theoretical output.

In weaving mills, output is usually measured in linear metres, which are converted into square metres whenever this is necessary for the comparison it is desired to make. To give an adequate indication of weaving output, the following are the minimum specifications required:

(a) Width of fabric on leaving the loom;

(b) Warp and weft yarn counts;

(c) Closeness of weave, i.e., the ends of warp and picks of filling in one unit of length.

On these bases, the weight per metre of fabric can be calculated, although some estimates still remain to be made, such as those relating to the number of threads in the selvedges and to warp and weft contraction.

The final stage in the weaving section is carried out on the loom, whose output - expressed in terms of length - depends upon the following factors:

(a) The number of picks of filling in the fabric per unit of length;

(b) Loom speed, which is expressed in terms of the number of picks per unit of time.[c/] Each pick corresponds to the insertion of one weft thread and an increase in the length of fabric equivalent to the inverse of the number of insertions;

(c) Machine efficiency, i.e., the ratio between real and theoretical output.

---

c/ In view of the mechanical limitations of the machine, especially as regards the driving of the shuttle, the speed of the loom depends upon its working width, the number of shuttles in operation, the automatic weft change system and the warp control system.

/From the

From the foregoing remarks, some idea can be formed of the endless number of variables which play a part in the production process in the textile industry, and of the need to disregard some of them, especially when the aim is to study the sector from the macro-economic standpoint. In the present survey, an attempt has been made to reduce to a minimum the distortions that may be introduced by the above-mentioned factors, and this accounts for the amount of detail that has had to be incorporated in some cases.

The fabric leaves the loom in a grey or untreated state, and therefore has to be subjected to a number of treatments, both physical and chemical, before it can be marketed. These treatments are given the generic name of "finishing", and also offer an almost infinite range of possible variations and combinations. In view of the complete independence of this stage of the manufacturing process, there is a marked tendency to execute it separately from the spinning and weaving processes, in plants engaged solely in finishing operations. Moreover, the technological development of this section of the industry, with the introduction of continuous processes and the consequent increase in the capacity of the production units, has still further conduced to its isolation from the rest.

Table A

MAIN CHARACTERISTICS OF PRODUCTS

Specification	Product A Coarse fabric	Product B Medium fabric	Product C Fine fabric
Yarn (warp and weft)			
Count	8's	18's	40's
Twist constant	4.25	4.00	3.80
Twist per inch	12	17	24
Type of cotton (Brazil)	Sao Paulo, 26 mm	Sertao, 30 mm	Seridó, 34 mm
Carded or combed	Carded	Carded	Combed
Fabric			
Width of cloth (cm)	80	90	100
Warp ends per centimetre	13	20	47
Filling picks per centimetre	10	20	32
Total number of warp ends	1 070	1 880a/	4 800
Contraction of warp (percentage)	1.0	7.3	8.3
Contraction of weft (percentage)	2.0	7.3	16.3
Weight per linear metre (grammes)	140	130	130
Warp	80	66	76
Weft	60	64	54
Weight per square metre (grammes)	175	144	130

a/ With triple selvedges.

Note: Estimate worked out on the following basis: Item 1. 2 months' production supply.
2. 10 day's production supply at cost of raw material and labour (including social security charges).
3. 5 day's production supply at cost of raw material and labour (including social security charges).
4. 2 per cent of value of equipment.
5. 1 per cent of annual cost of raw materials and labour (including social security charges).

thly salary.

Description	Classification	Hourly wage rate	Size I-2 000 spindles				Size II-6 000 spindles				Size III-30 000 spindles			
			Labour variable per shift			Total annual cost	Labour variable per shift			Total annual cost	Labour variable per shift			Total annual cost
			1	2	3		1	2	3		1	2	3	
I. Spinning														
A. Preparation (combing through reels)														
Spinner tender	V	0.35												
Piecer tender	V	0.35												
Card tender	V	0.35												
Card helper	V	0.25												
Card fixer	V	0.50												
Drawing (pre-combing)	V	0.35												
Lap tender	V	0.35												
Comber tender	V	0.35												
Drawing tender	V	0.35												
Roving tender	V	0.35												
Roving helper	V	0.25												
Oiler	V	0.25												
Sweeper	L	0.25												
Maintenance foreman	F	0.75												
Production foreman	F	0.75												
B. Spinning and winding														
Batcher	V	0.35												
Winder	V	0.35												
Doff piecer	V	0.25												
Prod. tender	V	0.25												
Doffer	V	0.25												
Steel roll cleaner	L	0.25												
Yarn tender	V	0.25												
Traveller changer	V	0.25												
Sweeper	L	0.25												
Maintenance foreman	F	0.75												
Production foreman	F	0.75												
II. Weaving														
A. Weaving through twister-in														
Weaver	V	0.35												
Additional weaver tender	V	0.25												
Yarn tender	V	0.25												
Slasher tender	V	0.35												
Additional slasher tender	V	0.25												
Size man	V	0.35												
Twister-in head	V	0.35												
Drawing-in head	V	0.35												
Oiler	V	0.25												
Sweeper	L	0.25												
Maintenance foreman	F	0.75												
Production foreman	F	0.75												
B. Loom section														
Weaver	V	0.35												
Battery hand	V	0.35												
Warp tender	V	0.25												
Cloth doffer	V	0.25												
Oiler	V	0.25												
Sweeper	L	0.25												
Maintenance foreman	F	0.75												
Production foreman	F	0.75												
III. Auxiliary services														
A. Maintenance														
Mechanic	F	0.50												
Electrician	F	0.50												
Welder	F	0.50												
Carpenter	F	0.50												
Workshop hand	L	0.25												
Boilerman	F	0.25												
Air conditioning mechanic	F	0.50												
Foreman	F	0.75												
B. Laboratory														
Sample collector	F	0.35												
Technician	F	0.35												
Assistant	F	0.25												
C. Miscellaneous														
Cotton storage hand	V	0.25												
Machine and tackle adjuster	V	0.35												
Roller coverer	V	0.35												
Unspecified	V	0.25												
IV. Administration														
Manager	A	0.50												
Engineer	A	0.50												
Technician	A	0.50												
Supervisor	A	0.50												
Office staff	A	0.50												
Sweeper and watchman	A	0.25												
Total fixed labour														
Total fixed labour														
Total variable labour														
Total administrative staff														

F = fixed; V = variable; A = administrative.

The total must be increased 20 per cent.

WORKLOAD PER OPERATIVE (IN TERMS OF PRODUCTION UNITS) ON WHICH MANNING-TABLE IS BASED

Machine	Production units per worker		
	Coarse fabric	Medium fabric	Fine fabric
Opening room			
Picker tender	2	2	2
Opener tender	2	2	2
Card			
Card tender	25	30	40
Card helper	20	20	20
Card fixer (one shift)	30	30	30
Drawing frame			
Drawing tender	10	12	16
Lap machine			
Lap tender	4	4	4
Comber			
Comber tender	4	4	4
Roving frame			
Roving tender	250	250	250
Roving helper	400	500	600
Ring spinning frame			
Spinner	1 600	2 000	3 000
Doffer	3 000	5 000	8 000
Cone winder (non-automatic)			
Winder	30	40	60
Pirn winder (automatic)			
Winder	60	80	120
Warper			
Warper tender	1	1	1
Assistant warper tender	1	1	1
Slasher			
Slasher tender	1	1	1
Assistant slasher tender	1	1	1
Loom			
Weaver	16	24	40
Battery hand	80	120	200
Maintenance foreman	200	200	200
Production foreman	400	400	400
Warp leader	200	300	500
Cloth doffer	200	300	500

a/ See tables HH, II, and JJ. Including administrative staff.
b/ 40 per cent of fixed labour costs.
c/ Linear depreciation over 40 years for buildings, and over 15 years for machinery at cost installed and ready to operate.
d/ Fixed maintenance cost, estimated at 1 per cent of the cost of the basic equipment.
e/ 12 per cent of total investment per annum; equivalent to the rate of interest normally paid on long-term loans.
f/ 3 per cent of fixed labour costs; including office supplies, communications, etc., but excluding publicity.
g/ Approximately 1 per cent of total fixed costs.
h/ See tables E to Z.
i/ 2 per cent of raw material costs.
j/ See tables E, I and J.
k/ 40 per cent of variable labour costs.
l/ Estimates based on a steam production cost of 1.5 dollars per ton and a consumption coefficient of 1.5 kilogrammes of steam per kilogramme of product in the slasher.
m/ Variable maintenance costs, estimated at 2 per cent of the cost of the basic equipment.
n/ Approximately 2.5 per cent of variable production costs.
o/ Approximately 1.5 per cent of variable production costs.
p/ Approximately 1 per cent of variable production costs.

a/ See tables HH, II, and JJ. Including administrative staff.
b/ 40 per cent of fixed labour costs.
c/ Linear depreciation over 40 years for building, and over 15 years for machinery at cost installed and ready to operate.
d/ Fixed maintenance costs, estimated at 1 per cent of the cost of the basic equipment.
e/ 12 per cent of total investment per annum; equivalent to the rate of interest normally paid on long-term loans.
f/ 3 per cent of fixed labour costs; including office supplies, communications, etc., but excluding publicity.
g/ Approximately 1 per cent of total fixed costs.
h/ See tables E to Z.
i/ 2 per cent of raw material costs.
j/ See tables H, I and J.
k/ 40 per cent of variable labour costs.
l/ Estimates based on a steam production cost of 1.5 dollars per ton and a consumption coefficient of 1.5 kilogrammes of steam per kilogramme of production in the slasher.
m/ Variable maintenance costs, estimated at 2 per cent of the cost of the basic equipment.
n/ Approximately 2.5 per cent of variable production costs.
o/ Approximately 1.5 per cent of variable production costs.
p/ Approximately 1 per cent of variable production costs.

Table 15

PRODUCTION FLOW CHART

(Product C: Size category VII)

Cotton warehouse
Daily consumption (kilogrammes) 18 645

Scutchers

Number of production units	5
Number of working hours per day	23
Daily output (kilogrammes)	18 396
Total waste (kilogrammes)	766
Waste recovered (kilogrammes)	-

Cards

Number of production units	54
Number of working hours per day	23
Daily output (kilogrammes)	17 476
Total waste (kilogrammes)	920
Waste recovered (kilogrammes)	50

Drawing frames (pre-combing)

Number of production units	16
Number of working hours per day	23
Daily output (kilogrammes)	17 389
Total waste (kilogrammes)	87
Waste recovered (kilogrammes)	80

Lap machines

Number of production units	6
Number of working hours per day	23
Daily output (kilogrammes)	17 302
Total waste (kilogrammes)	87
Waste recovered (kilogrammes)	80

Combers

Number of production units	25
Number of working hours per day	23
Daily output (kilogrammes)	13 842
Total waste (kilogrammes)	3 460
Waste recovered (kilogrammes)	-

Drawing frames I

Number of production units	26
Number of working hours per day	23
Daily output (kilogrammes)	13 773
Total waste (kilogrammes)	69
Waste recovered (kilogrammes)	60

Drawing frames II

Number of production units	26
Number of working hours per day	23
Daily output (kilogrammes)	13 704
Total waste (kilogrammes)	69
Waste recovered (kilogrammes)	60

Roving frames

Number of production units	1 130
Number of working hours per day	23
Daily output (kilogrammes)	13 636
Total waste (kilogrammes)	68
Waste recovered (kilogrammes)	60

Ring spinning frames

Number of production units	60 000
Number of working hours per day	23
Daily output (kilogrammes)	13 500
Total waste (kilogrammes)	136
Waste recovered (kilogrammes)	127

Cone winders

Number of production units	1 260
Number of working hours per day	23
Daily output (kilogrammes)	13 365
Total waste (kilogrammes)	135
Waste recovered (kilogrammes)	-

Pirn winders

Number of production units	750
Number of working hours per day	23
Daily output (kilogrammes)	5 585
Total waste (kilogrammes)	28
Waste recovered (kilogrammes)	-

Warpers

Number of production units	2
Number of working hours per day	23
Daily output (kilogrammes)	7 714
Total waste (kilogrammes)	38
Waste recovered (kilogrammes)	-

Slashers

Number of production units	3
Number of working hours per day	23
Daily output (kilogrammes)	7 676
Total waste (kilogrammes)	38
Waste recovered (kilogrammes)	-

Looms

Number of production units	1 280
Number of working hours per day	23
Daily output (kilogrammes)	13 261
Total waste (kilogrammes)	-
	-

Fabric warehouse
Total daily output (metres) 102 007
